We regret that our paper failed to make clear to Mr. Lippincott even the elements of its purpose. His statement that "the authors have gone into higher mathematics in order to work out the duty of water curves for different crops" is manifestly erroneous. We do not claim that our analysis looking toward the establishment of rational methods of interpretation of duty-of-water experiments is of any value in determining the time to irrigate. On the contrary we agree that an examination of the leaves and of the moisture conditions of the soil by means of borings with a soil auger are very good methods of determining when water is needed. For this purpose we use these methods on our own farms.

In order to use its limited water supply most economically the West must clearly have vastly more information. We agree with Mr. Crandall in the assertion that "engineers must share with the promoters the responsibility for many poorly conceived irrigation schemes" not so much because of a too ready use of experimental data as because of an unintelligent use of these data. Moreover, courts, water commissions, state engineers and other public organizations confronted with the problem of adjudicating water rights have had presented to them widely different interpretations of experimental data by authoritative men whose motives are genuine. These differences have resulted in part from the necessity of forming opinions upon the basis of insufficient analysis of the rather perplexing problem. It therefore seems reasonable to believe that a comprehensive analysis of the results of dependable duty-of-water experiments, in which consideration is given to the cost of the water and the land, the labor cost of producing the crop together with its sale value for a period of years and other closely related practical questions, may reduce to some extent the difficulty of approaching a correct solution of the problem.

Rapid Transit Railway at Sydney, Australia

Active work on the combined city underground and elevated line of the New South Wales Government Railways at Sydney, Australia, is outlined in the report of the Railway Commissioners for the year ending June 30, 1923. Part of the underground lines is cut-and-cover work, built in a trench made with an American dragline excavator and steam shovels. The remainder consists of double-track tunnels and twin tunnels, all with concrete lining. Part of the elevated line will be a six-track structure. Extensive works are required for stations and for connections with existing lines.

Again the English Channel Tunnel

A STATEMENT as to the project on a 27-mile English-French submarine tunnel under the Straits of Dover has been issued recently by Sir Percy Tempest, chief engineer of the tunnel company and also general manager of the Southern Ry., whose lines would connect with the tunnel. This project, of many years' standing, is kept alive by its promoters, although the British government persists in refusing to grant the necessary authority, largely for national and strategic reasons. According to the present statement, the material to be encountered for the entire distance is very favorable, being a deep bed of chalk marl, or chalk infiltrated with clay. That this material does not swell on exposure and is impervious is shown by the trial heading built in 1880-1881 and extending about a mile under the sea. With the boring machine designed for this work, and used experimentally, a heading 12 ft. in diameter can be driven at the rate of 120 ft. per day, and two machines started at opposite ends should meet in less than three years. It is proposed to complete this pilot tunnel or heading and then its enlargement to full section could be started at various points, so that the time for the completion of the concrete-lined tunnel is estimated at 4½ years. Instead of the usual mucking operations, the excavated material would be mixed with water to form a grout and then pumped to the surface. With present prices the cost is estimated at \$145,000,000. The annual revenue, based on existing traffic, would be more than 5 per cent of the cost, but it is expected that the tunnel communication would cause a great increase in traffic. A suggestion that a concrete caisson might be sunk in mid-channel for a working shaft with two additional headings is rejected by the engineer, partly on account of the extreme difficulty of sinking such a caisson in an open sea, subject to heavy storms, and with the danger of being struck by ships. Furthermore, with permeable strata and a hydrostatic pressure of 5½ tons per square foot there would be danger of water breaking through the seal at the bottom of the caisson and pouring through into the shaft.

Railway Relinquishes Water Supply Business

A water system operated by the Boston & Maine R.R. to serve its own water stations and a municipality has been sold to the latter, but under a contract which insures a supply to the railroad. This company had an investment of about \$15,000 in the Woodsville Aqueduct Co., which furnished water to the railroad at Woodsville and Wells River, N. H., and also to the village of Woodsville. The situation is stated as follows in the annual report of the Boston & Maine R.R.:

"Some dissatisfaction existed in the village because the water, although well suited for railroad purposes, was thought not to be suited for drinking water, and it was felt that it would be wise for the railroad to go out of the business of furnishing water and electricity. At the same time, it was necessary that the railroad should be assured of a sufficient supply of both at this point. The Aqueduct Company was formed in 1885 and had developed into a property of considerable value. Negotiations had been going on for some time, and early in 1922 the Woodsville Fire District voted to purchase the water-works system and plant of the Woodsville Aqueduct Co. The district further voted to contract to furnish the Boston & Maine R.R. with water and electricity for a term of twenty years,

Engineering Literature

A MONTHLY REVIEW OF BOOKS AND A LISTING OF NEW PUBLICATIONS

Relativity for Laymen

REVIEWED BY GEORGE PAASWELL

Specialist in Mathematical Engineering Problems, New York City
FOUR LECTURES ON RELATIVITY AND SPACE—By Charles Proteus Steinmetz, A.M., Ph.D., Past-President, American Institute of Electrical Engineers. New York and London: McGraw-Hill Book Co. Cloth; 6x9 in.; pp. 126; 32 line cuts and halftones on cards in pocket. \$2.

Dr. Steinmetz has evidently joined the throng of those, who, having accepted Relativity, become fired with a holy zeal to make all laymen converts to the theory. It is a very ambitious task to render a popular account of Relativity and it is surprising to note how convincing many of the explanations appear in the course of the lectures. However, it is only just to state that the author meets far greater success in demonstrating the significance of relativity than in exhibiting its plausibility.

There has arisen a classic method of explaining the new doctrine, founded upon its historical development. Starting with the failure of the Michaelson-Morley experiment to demonstrate motion with respect to the ether, the unique postulate of the shortening of time and space measures made its appearance. Then came the theorem of special relativity, that it is impossible to determine uniform motion with respect to the ether. There followed the fundamental law that the velocity of light is the same to all observers regardless of their reference system of co-ordinates. This is true merely because its converse would permit determination of motion with respect to the ether.

In contrast the author starts with two simple premises: (1) All phenomena of space, time and motion are relative, and (2) All laws of nature are universal. On their face, these two statements are easily acceptable, but, as a matter of fact, there is not enough in the two to premise the relativity theory upon, and the fundamental statement following these two premises, that the velocity of light is everywhere constant, appears rather as a contradiction than as a consequence of the premises. Relativity is founded upon an entirely novel conception of physical law and little is gained by attempting to reconcile Newtonian mechanics or our slightly ramified conceptions of space with the new theory. That the velocity of light is constant, regardless of the reference frame used, is a unique assumption not met with anywhere in the domain of physical law heretofore, and it seems unfair to the reader to attempt to slip such a law by him without, at least, pointing out such uniqueness.

It is all very well to give the usual examples of the bullet and the moving train and the observer fixed upon the earth but one should frankly admit that these simple analogies do not lead to an acceptable explanation of relativity. Such relative motion has always been accepted and completely understood. However, the author has really given a brilliant demonstration of the equivalence hypothesis—the equivalence of the gravitational field with a simple transformation of acceleration axes—and his examples there are exceedingly well chosen. As a general conclusion, drawn by the reviewer after hav-

ing read a number of attempts to explain in a popular sense what relativity is, it seems far better to cling to a simple mathematical statement of the space of relativity and then to convince the reader that, due to the soundness of the mathematical demonstrations and to the experimental confirmation of the fundamental premise, the conclusions of relativity are correct.

Lectures 2 and 4, on Space Properties, are of exceeding interest and the geometry and other characteristics of the space described should certainly arouse sufficient interest in the reader to make him want to learn more of non-Euclidean geometry. As one notes the almost universal acceptance of the demonstration of the curvature of the high space by simply stepping up the formulas from two dimensions onward, there is an uneasy feeling that the mathematicians are justly irritated in the forced analogy between the space geodesics of Euclidean geometry and the properties of the world lines in the new space. In the long run it may be that the analogy will confuse rather than illuminate the properties of these new space "invariants."

On the whole one feels that the new book is a very stimulating contribution to the so-called popular treatises on Relativity and it is hoped that when the reader has finished it he will take up some of the more serious texts—Eddington's first report, Weyl (as translated into English), Silberstein, Cunningham, Robb and others.

Co-operation Instead of Conflict

INDUSTRIAL DEMOCRACY: A Plan for Its Achievement—By Glenn E. Plumb and William G. Roylance. New York: B. W. Huebsch, Inc. Cloth; 6x8 in.; pp. 359; frontispiece portrait of senior author. \$2.

Some two years ago the late Glenn E. Plumb attracted country-wide attention by his plan for the nationalization of our railways. The plan was heartily approved by the various railway brotherhoods and received a warm welcome from organized labor generally and more or less endorsement by advocates of public ownership of all utility monopolies. Opposition, as was to be expected, came from representatives of the railways and of capital as well as from that part of the general public which was ready to protest that government operation of the railways, express, telegraph and telephone services during the war had been unsatisfactory.

Full of confidence in the underlying principles of his plan for the railways, Mr. Plumb went on with an elaboration of the application of those principles to all industry. In this he had the co-operation of W. G. Roylance. The result is this book on Industrial Democracy, the text of which, as the foreword states, "was in a finished state at the time of Mr. Plumb's death." The foreword adds: "The form and content of the book, arrangement of material and general philosophy resulted from earnest collaboration. The known familiarity of Mr. Roylance with the problems of agriculture, public finance, banking, currency, credit, and their relation to industrialism gives authentic value to their treatment."

Regardless of one's opinion as to the causes and remedies for the industrial conflicts, cycles of prosperity and depression, this book deserves wide and careful reading. It is no wild-eyed or wild-minded vision of a mere dreamer; nor of a man bent on bringing all capital and industry within the control of any one class, large or small. Instead, it is a carefully reasoned argument for applying what the author conceives to be the fundamental principles of democracy, as set forth in the Constitution of the United States, to the production and distribution of all goods and the conduct of all services required to satisfy human needs, including, particularly, financing these enterprises.

The substitution of a thoroughly democratic co-operation of all contributing in any way through labor, managerial ability, or accumulated capital in money or other form for the present endless conflicts between the respective contributors, each for his own gain, regardless of the interests of the rest, is the basic idea of the book. Organized industry is now conducted for profit rather than for production to meet human needs, the book holds. Moreover, the control of industry, it is maintained, is vested largely and almost overwhelmingly and increasingly in capital which operates from without instead of from within the industry and without any specific knowledge of the industries controlled. The mass of the producers has no part whatever in the control of industry, except as gained through strikes, actual or threatened.

Profits, the book holds, are abstracted from industry to pyramid capital on which the whole effort is to earn more and more profit. If a larger and due part of these profits went to the mass of producers, the book holds, then their consuming capacity would be increased and with it the market for commodities. Instead, the argument runs, capital demands absorb the purchasing power of the mass of producers so that from time to time goods pile up, wages are cut or employees let go, and the purchasing power of the mass of producers so curtailed results in the stagnation of industry.

Under Mr. Plumb's conception of industrial democracy, co-operation in production would be secured, not by abolishing private corporations and attempting any sort of communism, but through corporations organized on a thoroughly democratic basis. Under this plan every one engaged in production would share in both the control and the profits of industry in direct proportion to what each individual and each class contribute. The consuming public would be a partner in benefit but not in management. The returns to money capital would be some established percentage of the amount of money contributed to the enterprise. Voting for corporate management control would be proportioned upon the dividends paid to capital on the one hand and on the other upon the salaries and the wages paid to management and to labor. A part of the profits would go to the reduction of capital loans and a part into the business. Eventually outside capital loans might all be paid off. When profits exceeded all charges, including an established rate of return on the investment, prices for goods produced would be cut, thus making the consuming public a partner in the enterprise. By such means, the authors believe, the great waste in industry through the struggle between the present conflicting interests would be eliminated and economic and industrial efficiency obtained, together with individual and social justice.

The book contains a plan for operating the coal industry and plans for the benefit of agriculture, for market, for credit, for foreign trade—the latter also to be based on the principles of industrial democracy.

As might be expected from a book of propaganda, the book contains many dicta and allegations with little or no supporting data or documentary references. A wide reading of the book is to be hoped for, as it is full of food for thought. Whatever the fate of the plan so well presented may be, many of its underlying principles and supporting arguments are incontrovertible and are bound to be accepted in some part as the years go by.

Railway Maintenance

REVIEWED BY S. B. McCONNELL

District Engineer, Canadian Pacific Ry., North Bay, Ont.

PRACTICAL RAILWAY MAINTENANCE—By Charles Weiss, C.E. New York and London: McGraw-Hill Book Co. Cloth, 6 x 9 in.; pp. 343; many line cuts. \$3.50.

The author appears to have attempted to produce a volume suitable both for the student and the man of experience in railway maintenance. Although a great deal of information is presented much of it is of doubtful value to the man of experience. As for the student, while the book might be interesting it would, in some instances, prove misleading inasmuch as it evidently cites practices which, although suitable under certain conditions would be considered of questionable merit under others. A guide to beginners, who cannot be expected to have the knowledge at their disposal to enable them to discriminate between the conditions under which the rules laid down should or should not be followed, should state, where rules are not universally suitable or even suitable throughout this continent, under what conditions—as of climate or traffic—they should apply.

To cover railway maintenance in a manner to be of material value to those outside a limited area, the author's viewpoint should be based not only on a wide and varied personal experience, but also on a study of the experience of others under conditions beyond his own experience. In the case of this book one is forced to the conclusion that the viewpoint of the author is limited and the book of value only to those confronted with the same conditions. The following extract from page 11 is an example to support this conclusion: "Use the fall for final surfacing, lining, tie renewals and similar work, leaving the gaging for winter." This program may and no doubt does meet the requirements where the author has received his experience, but where winter means continuous frozen ground from November to May, as well as a heavy covering of snow throughout the most of this period, it would obviously be bad practice to leave the tie renewals until fall, as there would then be no opportunity to do the final surfacing before the freeze up; and as for the gaging, if left for the winter, there would be the added expense of removing the snow when every hour of labor available is required for shimming, bracing and other work resulting from the frost action. Under such conditions shimming could not be carried out as suggested on page 70.

The value or correctness of many other statements is open to question, but a single illustration will serve to show that this work is not based on a broad knowledge of railway maintenance.

English and the Engineer

ENGLISH FOR ENGINEERS—By S. A. Harbarger, Dept. of English, Ohio State University, Member, Committee on English, Society for the Promotion of Engineering Education, New York: McGraw-Hill Book Co., Inc. Cloth; 5 x 8 in.; pp. 266. \$2.

The importance of the correct use of English in the success of the engineer is clearly set forth in this book, directed mainly to the undergraduate engineer and written purposely as a textbook. Properly studied, it should be most valuable to the embryo engineer, particularly if he takes to heart the author's true words: "A man's language is taken by most to indicate not only his literacy but also his background, the grade of society in which he has placed himself, his tastes, his aspirations, his diligence and his appreciation."

The letter, the wire communication, the explanation—of a design, a process, a piece of construction—the abstract, the report, and also conversation are the means whereby the engineer may sell his professional knowledge and ideas. The aim of this book is to develop in engineering students, who frequently pay too little attention to English while in college and regret it when they come to practical work, the ability to have something definite to say and to say it concisely and clearly.

While there are no exercises in the book, specifically for classroom study in engineering schools, there are plenty of references to sources for such material. The volume is also well supplied with examples and models for all the forms of writing discussed, the models being taken from books and from the leading technical journals of the day. Emphasis is laid throughout the book on the value of correct expression, even in the paper and envelope transmitting a letter, and on the importance of self-analysis to be sure that one has something the recipient will want to hear before he sets himself to letter or engineering report, article or editorial.

One feature that is interesting is the stress laid on oral discussion in society meetings, undergraduate as well as later professional. Too little attention is usually given in English work to oral expression, and to insist on attention at and participation in engineering society meetings as a means of developing proficiency in speaking while not a novel idea is one well worth emphasizing to the undergraduate.

The Writing of Briefs

BRIEF DRAWING—By Ralph Curtis Ringwalt, A.B., LL.B.; Member of the New York Bar. New York and London: Longmans, Green & Co. Cloth; 6x8 in.; pp. 214. \$1.50.

In the logical marshaling of the main facts bearing on an engineering project, the engineer may often profitably follow the same general theory and practice as is followed by the lawyer in preparing a brief. This little book presents in small compass the fundamentals of brief drawing, as they appear to a lawyer who has both taught and practiced law. Emphasis is laid on one essential which every novice, whether in law or in engineering, must realize if he is to succeed: A brief, argument, or report must be drawn to convince the class of person to whom it is addressed.

After defining a brief, the author considers library research, reading and note taking, argumentation, the audience, and various phases of proof and evidence. He then analyzes brief drawing, including among other things the various classes of paragraphs, the introduction, the argument, the conclusion. A model brief closes the book.

The volume should be suggestive to professors in engineering schools and useful both to students of engineering and to many a practicing engineer.

Kent's Handbook Largely Rewritten

KENT'S MECHANICAL ENGINEERS' HANDBOOK—By the late William Kent, M.E., Sc.D., Tenth Edition, Rewritten, by Robert Thurston Kent, M.E., editor-in-chief, and staff of specialists. London: Chapman & Hall, Ltd. New York: John Wiley & Sons. 41x7 in.; pp. 1,247; line cuts. Flexible binding, \$6.00 net; leather, \$7.00 net.

The tenth edition of Kent's well-known Handbook has been largely rewritten. It contains much new text and many new tables. There is considerable new information on heat and heat insulation, fuels and combustion, air compressors and condensing equipment, power transmission and electrical engineering; considerable information in regard to railroad engineering with special reference to train resistance and locomotive design; and much new material in the section on machine design. The sections on fans and blowers, hydraulic turbines, pumps and pumping engines, steam engines and steam turbines, oil engines and gas producers, hoisting and conveying equipment, refrigeration and ice-making, and heating and ventilation have been entirely rewritten. New sections include gas turbines, automotive vehicles, aeronautics, fusion welding and cutting, malleable casting, reinforced concrete, and safety engineering.

PUBLICATIONS RECEIVED

ILLUSTRATIONS and some text have been added to the second edition of Special Assessments, a Means of Financing Municipal Improvements, by the Committee on Sources of Revenue, National Municipal League, 261 Broadway, New York City. (Technical Pamphlet No. 15; pp. 21; 25c. cash or \$15 a hundred.)

THE INCREASING ACTIVITIES of state health departments in the field of applied sanitation, particularly in the South, is illustrated by a 45-p. pamphlet on The Operation of Water Filtration Plants of the Mechanical Gravity Type prepared by the Bureau of Engineering and Inspection of the North Carolina Board of Health (Raleigh). Half of the space is occupied by plain directions for filter operation, plant records, etc., and half by a description of chemical and physical tests for general filter, chlorine, bacteria and hydrogen-ion control.

THREE CONTRIBUTIONS to the June *Monthly Weather Review* (issued in September) will appeal to engineers: (1) Robert E. Horton, consulting hydraulic engineer, Voorheesville, N. Y., fills 15 pp. with a discussion of Rain-fall Interpolation, accompanied by tables and diagrams; (2) Prof. Peter Philipovitch Gorbatcher, Rostov on Don, Russia, has some 4 pp. Concerning the Relation Between the Duration, Intensity, and the Periodicity of Rainfall; and there is a short paper on City Planning and the Prevailing Winds, by Clarence J. Root, meteorologist, Weather Bureau Office, Springfield, Ill.

A NATIONAL PLAN STUDY BRIEF, consisting of brief text and a number of striking diagram-maps of the United States, has been reprinted and is available in the form of a 24-p. Supplement to *Landscape Architect* (Cambridge, Mass.) for July, 1923. The author is Warren H. Manning, landscape and city planning consultant, Boston, Mass. The text deals chiefly with the natural resources and other opportunities afforded by the United States and the need of a national plan for their fullest and wisest utilization. The map-diagrams show our river and mountain systems; crop regions; original and present forest areas; rainfall totals by districts, with arid, semi-arid, irrigable and humid areas; lands improved and unimproved; soil in relation to

agriculture; factory centers; coal and lignite and also peat deposits; minimum potential water power by states; railroads; commercial and recreation areas and connecting ways; rural population per square mile, and national and state reservations—all of which may be characterized as a grand preliminary survey.

TRIBUTES TO THE LATE DR. HERMANN M. BIGGS, for several years health commissioner of New York State, are found in *Health News* for July, recently issued. Among the contributors outside of his one-time associates in the New York City and State health services are Prof. C.-E. A. Winslow, Yale University; Dr. Hugh S. Cumming, Surgeon-General, U.S.P.H.S.; Dr. Charles V. Chapin, superintendent of health, Providence, R. I.; Prof. George C. Whipple, Harvard University, and Dr. E. C. Levy, president, A.P.H.A. (Albany, N. Y.: State Department of Health.)

USEFUL INFORMATION designed "chiefly for the practical miner or small operator" is given in *Timbering of Metal Mines*, by E. A. Holbrook, Richard V. Ageton, and Harry E. Tuft. One or more methods for each timbering operation are given. (Washington D. C.; Bureau of Mines; one copy free.)

PUBLIC HEALTH BULLETIN No. 135 on Railroad Malaria Surveys, 1922, the Missouri Pacific Railroad, by A. W. Fuchs, associate sanitary engineer, U. S. Public Health Service, reviews malaria presence among employees and the effect of malaria on operating costs and railroad revenue, and presents a malaria control program. (Washington, D. C.; Public Health Service; one copy free.)

HIGHWAY INSTRUCTION IN ELEMENTARY SCHOOLS, designed to give also instruction in science, geography, civics, history and literature, is outlined in a 42-p. illustrated pamphlet, *Main Streets of the Nation*, by Florence C. Fox, specialist in educational systems, Bureau of Education (Washington, D. C.).

THE TWENTY-FIFTH SPECIAL REPORT of the National Industrial Conference Board (10 E. 39th St., New York City), on Engineering Education and American Industry, has sections on (1) the need for trained leadership in industry; (2) the educational problem and (3) the responsibility of industry. Under (2) there are discussed: the engineering school, tendencies in engineering courses, suggestions from industrialists, training in fundamentals, and selection and classification of students.

UNDER THE TITLE "Some Compressive Tests of Hollow-Tile Wall," by H. L. Whittemore and B. D. Hathcock, the Bureau of Standards (Washington, D.C.) has issued Technologic Paper No. 338, describing strength tests on tile walls 6, 8, and 12 in. thick, and 4 ft. long by 12 ft. high. It contains some excellent detailed information on this type of construction.

THE AMERICAN WELDING MILL Co., of Middletown, Ohio, has issued a little book entitled "River Shipping in Industry," which is a compilation of historical and river shipping data on the Ohio River and its tributaries. It is frankly in advocacy of waterways transportation, but it seems to be valuable as a directory of the Ohio River district.

Foreign Papers and Reports

THE ADDITIONAL WATER SUPPLY for Johannesburg and five other "magisterial districts" in the Transvaal, South Africa, comprising a total population of about 600,000, is described in a Souvenir of the Opening of the Vaal River Scheme—an illustrated pamphlet written chiefly by W. Ingham, chief engineer, Rand Water Board, Johannesburg. The works described include an impounding reservoir of over 16 billion U. S. gallons capacity, a low-lift pumping plant, settling basins, mechanical filters with a capacity of 6.4 m.g.d. (Imp.), a clear-water reservoir and high-service pumps delivering water under a 480-ft. head through a 261-mile force main. After the water thus delivered has been mixed with an underground supply in a reservoir it is again pumped, part under an 820- and part under an 1,100-ft. head, a further distance of 14 miles to high-service reservoirs.

ANOTHER OCCASIONAL DESCRIPTION of the Works of the Birmingham, Tame and Rea District Drainage Board, by John D. Watson, chief engineer (Birmingham, England), has appeared. Altogether three plants treat the sewage of a little over a million people, chiefly from Birmingham. The main sewage-works, dealing with the sewage from a population of about 900,000, is and long has been one of the most interesting plants in the world. It includes detritus, storm-water, sedimentation, balancing, silt, separate sludge digestion, and final sedimentation tanks, together with bacteria beds (percolating filters, which receive the clarified sewage) and sludge drying beds. Besides describing all three of the plants Mr. Watson devotes a few pages to two activated-sludge units and a percolating filter, each of 12,000 U. S. gal. daily capacity. One of the activated-sludge plants depends on compressed air and the other on mechanical agitation for activation, and each treats tank-settled sewage. The tests thus far made indicate, Mr. Watson says in effect, that either method of activation may be used successfully on Birmingham sewage; that tank liquor is better than crude sewage for activation; that one hour of "efficient flocculation" removes 60 per cent of "the impurity" and all "objectionable smell" from the tank effluent and "produces a liquor which may be oxidized at more than double the present rate on a percolating filter."

New Books and Revised Editions

BLUEPRINT READING: For the Machine Shop and Related Trades—By Joseph Brady, B.S., C.E., Brooklyn Vocational School, and Brooklyn Evening Technical and Trade School, New York; D. Van Nostrand Co. Cloth; 11 x 8 in.; pp. 18; 134 halftones and line cuts on blue. \$2.50.

ELASTICITY AND STRENGTH OF MATERIALS USED IN ENGINEERING CONSTRUCTION: Section III, Theory of Tension in Shafting, and Double Bending of Plates—By C. S. Turner, Consulting Engineer, M.Am.Soc.M.E., M.A.S.T.M., M.S.P.E.E., M.Am.Soc.E.E. Minneapolis, Minn.: Published by the Author. Cloth; 6 x 9 in.; pp. 122; 132 line cuts. \$5.

THE ELEMENTARY PRINCIPLES OF LIGHTING AND PHOTOMETRY—By John W. T. Walsh, M.A. (Oxon), M.Sc. (London), A.M.I.E.E., F. Inst. E., Member of International Illumination Committee of Great Britain, General Secretary of International Commission on Illumination, Senior Assistant in Photometric Division of the National Physical Laboratory; with a Foreword by Sir J. E. Petavel, K.B.E., F.R.S., D.Sc. Cloth; 6 x 9 in.; 85 diagrams by G. H. Lewis. \$4.50.

FIRE LOSSES: LOCOMOTIVE SPARKS—By L. W. Wallace, M.Am.Soc.M.E., M.Soc. Industrial Engng.; Executive Secretary, American Engineering Council of the Federated American Engineering Societies; former Professor, Mechanical Engineer, Purdue University, New York: Barr-Eberhart Press, Inc. Flexible; 6 x 9 in.; pp. 203; 111 halftones and line cuts. \$3.

Gives the result of five years' study of the relation of locomotive sparks to fires occurring along railroad rights-of-way. Covers the fundamental locomotive construction and operation from the standpoint of spark control, the effect of design and of spark-arresters, the distribution and character of sparks, and their ability to ignite combustible material.

HYDRAULICS APPLIED TO SEWER DESIGN—By G. S. Coleman, D.Sc. Eng. (London), Assoc. M.Inst.C.E., Associate Member of the Institution of Municipal and County Engineers, Senior Lecturer in Municipal and Sanitary Engineering in the Municipal College of Technology, Manchester, England, and Assistant Lecturer in the same subjects in the Victoria University of Manchester. London: Crosby Lockwood and Son, New York: D. Van Nostrand Co. Cloth; 5½ x 8½ in.; pp. 150; 70 line cuts. \$4.

MEMOIRS: With a Full Account of the Great Malabar Problem and Its Solution. By Fernald Ross. New York: E. P. Dutton & Co. Cloth; 6 x 9 in.; 11 plates. \$9.

MOVABLE AND LONG-SPAN STEEL BRIDGES—Compiled by a Staff of Specialists: Editors-in-Chief, George A. Hool, S.E., Consulting Engineer, Professor of Structural Engineering, University of Wisconsin; and W. S. Kinne, B.S., Professor of Structural Engineering, University of Wisconsin. New York: McGraw-Hill Book Co., Inc. Cloth; 6 x 9 in.; many halftones and line cuts. \$5.

SOUTHERN YELLOW PINE: A Manual of Standard Wood Construction. Ninth Edition. New Orleans, La.: Southern Pine Association. Flexible; 5x7 in.; pp. 186; line cuts. \$1.50.

Material added in this edition "includes timber working stresses based on recent extensive tests, new matter affecting the design of latticed wood trusses, and the calculation of nailed and bolted timber construction. By Municipal and state building codes have been omitted because of the difficulty of keeping these revised to date, to keep the Manual of convenient size, and because the Southern Pine Association looks forward to a national building code. The volume contains many tables and diagrams and much other material of value to southern pine users."

A TEXT BOOK OF FILTRATION: Industrial Filtration and the Various Types Used—By Charles L. Bryden, E.M., B.S., and George D. Loecky, B.S., Easton, Pa.: The Chemical Publishing Co. Cloth; 6 x 9 in.; 264 halftones and line cuts. \$5.50.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Bates Road Tests and City Streets

Sir—There appeared, in *Engineering News-Record*, Sept. 6, 1923, p. 399, under the heading, "Bates Road Tests Do Not Apply to City Streets," an article by Ivan Houk, criticizing the reports on the Bates test road. They have not, he said, made clear that the conclusions drawn do not apply 100 per cent to city pavements.

The Bates road tests having been made under certain conditions, we would not dream of supposing the conclusions drawn to apply to other conditions. It is the engineer's job to know the conditions he has to contend with. The conclusions drawn from one set of conditions and results must be modified before being applied to a different set of conditions.

The impression that the design of slab adopted by Illinois was intended to strengthen the edges of the pavement more than the middle, is wrong. Reports clearly state that it was intended to make them *as strong*. Whether the bulk of heavy traffic runs at the side or on the middle little affects the design. Remembering that it was the last straw which broke the camel's back, we design to prevent, as far as possible, a broken pavement, by making the slab uniform in strength throughout—strong enough to take care of stray loads as well as the more frequent ones. This condition is obtained, in our state roads, by thickening the edges until they are as strong as the middle.

One method suggested, in the Bates road reports, to protect the edges of pavement was to use curbs. These are used with city pavements, and although constructed for other reasons, they still may have this further use. But we cannot guarantee that heavy traffic will not run to the side of the street, and we would feel inclined to make the sides, as well as the middle of the street, strong enough to carry it.

There are however many features in city streets which call for more particular design. Slabs of uniform thickness are weakest at the corners and in city streets we may at times encounter corners which unquestionably will be subjected to maximum loads and maximum stresses. For example when a street-car track runs out a spur line, forming a terminus, there will be several pavement corners in the middle of the street.

The support of the subgrade in city streets would normally be better than in state roads, but the Bates road tests showed that owing to temperature changes causing the slab to warp, the pavement lifted clear of the subgrade. The amount of warping varies considerably with different types of pavement. How much this takes place in city streets should be ascertained by tests; it may be responsible for failures on a well prepared subgrade. In state highways, it is an important factor in design.

In short, the subject of city paving was not specifically within the scope of the Bates road tests, and the reports were not intended to discuss or compass it. Each pavement must be designed to meet its own peculiar requirements, and however much these individual requirements may vary, there will still be many properties in common to all pavements, and the designer of city streets may still benefit from the tests conducted at the Bates experimental road.

HADDON C. ADAMS,
Assistant Highway Engineer, Illinois
State Highway Commission.

Springfield, Ill.,
Oct. 1, 1923.

Further Discussion of Low-Head Pumps

Sir—I was, naturally, much interested in the letter by M. C. Steuber appearing in your issue of Sept. 20, p. 486, which I take occasion to answer because certain statements by Mr. Steuber are misleading and should be cleared up both to him and to your readers. I wish it to be understood that my statements herein are made only in the spirit of friendly criticism and are meant to bring out the facts clearly.

It is to be noted that in my article in the Aug. 9 issue, p. 230, I drew comparison with other pumps of the same size as my model, operating at equal capacities against equal heads. To those who understand the subject it is unfair to draw comparisons without taking account of all these factors. However as Mr. Steuber has drawn a direct comparison I shall take him up without any apology for size and make a direct comparison myself, as a very important feature was overlooked.

A very little study discloses the fact that the Malde pump described never gave a discharge velocity of over 5.1 sec.-ft. (usually called spouting velocity) and only gave this at 1-ft. lift and at 650 r.p.m., which I judge means a peripheral speed of 45.5 ft. per sec. of the impeller. The velocity head of the water only once reached .403.

The Malde pump showed 40 per cent at 3-ft. lift with a spouting velocity of 3.16 sec.-ft. whereas the rotary flow for the same conditions of lift and efficiency gave a spouting velocity of 7.6 sec.-ft. or 2.4 times as much as the Malde. At 5-ft. lift the Malde shows 39 per cent efficiency with a spouting velocity of only 3.5 sec.-ft., whereas the rotary flow shows 36 per cent with a spouting velocity of 9.7 sec.-ft. This is 2.77 times great as the Malde. At 6-ft. lift the rotary flow shows 39 per cent efficiency with a discharge spouting velocity of 9.2 sec.-ft., whereas the Malde with 38 per cent efficiency shows only 3.25 sec.-ft. Again, the rotary flow, for equal conditions of efficiency and head, gives a rate of discharge (spouting velocity) 2.84 times as great as the Malde.

This proves conclusively the superiority of the rotary flow without reference to the difference in size which I will now take up.

From a comparison of the friction losses in 4-in. and 16-in. pipe, using the figures for 100-ft. lengths in a standard table, it would appear that a 4-in. casing with a spouting velocity of 9.5 sec.-ft. should lose 31.6 times as much head due to friction as a 16-in. casing of equal length. Due allowance should be made for this in making comparisons.

A 16-in. pump at a 6-ft. lift and a spouting velocity less than 6 sec.-ft. should give not less than 80 per cent. It has been done. If the rotary flow under this low condition of capacity did not do as well I would be greatly disappointed.

The fault in the Malde pump, unfortunately, is inherent in the design; and, short of radical changes in this, it cannot be expected to give much higher efficiencies, especially if the rate of discharge is increased, in which case it would be expected to fall off.

With regard to the test curves, I will say for Mr. Steuber's benefit that though only two tests were shown, these are typical of twenty run under widely varying conditions.

The discharge characteristics were predicted, and so were the efficiencies and high speed and the horsepower curves and furnished no surprise on test. What did furnish a little surprise was the ability of the pump to operate with a pipe velocity of only 1.5 ft. per sec. on the higher lifts at a very high peripheral speed without cavitation.

While the Malde was not run at over 45.5 ft. per sec. peripheral speed, one incomplete test was run at 72 ft. per sec. peripheral speed with the rotary flow with an increased discharge but no other difference from other tests. This test was not finished because the writer lost his nerve at the sight of a 650 r.p.m. motor running 2,500 r.p.m.

I believe that the above covers all of Mr. Steuber's questions and I thank him for his interest in this subject.

EUGENE F. DELÉRY,
Design Engineer.

New Orleans, La.,
Sept. 30, 1923.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

Am. Soc. C. E. Board Acts on Davis' Dismissal

Special Committee Report Accepted
Recommending Protest Letter Be
Sent Dr. Work

Engineering News-Record Staff Report

Preceding the fall meeting of the American Society of Civil Engineers at Richmond, Va., Oct. 17-20, twenty-six of the twenty-eight members of the Board of Direction of that society on Oct. 16 took decisive action in the matter of the dismissal of A. P. Davis from the Reclamation Service. The Board accepted the report of a special committee composed of John F. Stevens and George S. Webster, recommending that a letter be sent to Secretary of the Interior Work protesting against his contention that an engineer is not competent to conduct administrative positions, and citing examples wherein engineers have become famous through their executive abilities. The letter will also demand from Secretary Work specific citations of the failure of engineers in reclamation work. It will probably also demand congressional action looking toward the assurance that an engineer will be responsible for government irrigation.

The Board of Direction may attempt, it was brought out, to bring about Congressional action looking toward the appointment of a many-sided technical commission to investigate and report upon the whole question of the development of the St. Lawrence River for power and navigation uses.

EARTHQUAKE COMMITTEE FORMED

A committee to investigate the earthquake in Japan was appointed, to be headed by the following California members of the society: J. D. Galloway as chairman, C. H. Snyder, and C. B. Wing. It is probable that Japanese members will be added.

Definite action regarding the formation and activities of the proposed committee on cement was put over until the January meeting of the society. The report of the licensing committee was received but has not yet been adopted or made public. However, without endorsing the principles of registration, the Board recommended that in view of the many state laws the profession should indorse a uniform law, and the standing committee was authorized to prepare such a law.

New procedure decided upon for the professional conduct committee will be for the secretary of the society to prepare an unbiased brief in the matter of any professional dereliction brought to the attention of the society. The committee will then study the case and report confidentially to the Board, which shall then decide whether or not the case is to be made public.

Prizes for the past year were awarded as follows: Norman medal, D. B. Steinman, for paper on "Locomotive Loading for Railway Bridges"; James J. R. Croes medal, James F. Sanborn, for

Flood Cuts Embankment of Oklahoma Reservoir

A flood of greater volume than the one which swept down the North Canadian River in Oklahoma last June and overtopped the dam of the reservoir of Oklahoma City has again overtopped the dam and embankments and has cut a channel 350 ft. wide through the embankment at the west side of the reservoir.

The Oklahoma City reservoir is located in the valley of the North Canadian River about eleven miles above the city. (For a description of the dam and of the flood of June, 1923, see *Engineering News-Record*, March 4, 1920, p. 478 and Aug. 23, 1923, p. 292.) The reservoir is formed by a reinforced-concrete dam and spillway and an earth fill dam with a concrete core-wall across the main channels of the river. A bypass channel and emergency spillways were provided to take care of floods. Beyond the west end of the earth fill dam is a low embankment protected along part of its length by a gunite mat. According to a report from C. E. Bretz, superintendent of the city waterworks department the crest of the flood was 27 in. above the top of the dam when the river started cutting through the embankment at the west end of the dam. A futile attempt was made to save the embankment by the use of sand bags.

The flood followed a rainfall of nearly 6 in. which started on Oct. 12. The embankment failed at 12:25 a.m. Oct. 16, 1923.

paper on "Engineering Geology of the Catskill Water Supply" (this was a joint paper written by Dr. C. P. Berkey and Mr. Sanborn, but as Dr. Berkey is not a member of the society, the award was made to Mr. Sanborn); Thomas Fitch Rowland prize, S. W. Peek, Jr., for paper on "High-Voltage Power Transmission"; James Laurie prize, R. W. Gausman and C. M. Madden, for paper on "Experiments with Models of the Gilboa Dam and Spillway"; Arthur M. Wellington prize (first award, the prize having been established in 1921 by *Engineering News-Record*), J. P. Newell, for paper on "Analysis of Cost of Freight Service, Grand Trunk Railway Co. of Canada"; Collingwood prize for juniors, Jacob Fels, for paper on "Accurate Experimental Determination of the Lateral Earth Pressure Together with a Resume of Previous Experiments."

Two honorary members were elected to the society, though neither has made formal acceptance of the election. They are Onward Bates and Desmond Fitzgerald, both past presidents of the society.

Coming meetings of the society were arranged as follows:

1924: spring meeting, Atlanta, Ga.; summer meeting, Pasadena, Calif.; fall meeting, Detroit, Mich.

1925: spring meeting, Cincinnati, Ohio; summer meeting, Salt Lake City, Utah; and fall meeting Montreal, Que.

Army Camp Builders Demur to Fraud Indictments

Defendants Ask Cases Be Thrown Out
Contending Indictments Charge
No Crime

A demurrer to the indictments of Benedict Crowell, W. A. Starrett, C. W. Lundoff, Morton C. Tuttle, Clair Foster, James A. Mears and John H. McGibbons, charging conspiracy to defraud the government in connection with building army cantonments, was argued before Judge Hoehling, of the District of Columbia Supreme Court, during the first two weeks in October. The principal counsel for Mr. Crowell and his associates were Frank J. Hogan, of Washington, and Col. Henry L. Stimson, formerly Secretary of War under the Taft Administration. The government was represented by ex-Congressman McCullough of Ohio and W. T. Chantland, both of whom have been connected with the Department of Justice in the preparation of the indictments, and by U. S. District Attorney Peyton Gordon.

ASK DISMISSAL

The defendants combined in asking that the indictment be dismissed on the ground that it charged no crime, but based an allegation of fraud solely on the opinion of the present Department of Justice regarding the wisdom of a governmental policy; that is, the making of cost-plus contracts for the construction of the army training camps. Counsel defied the Department of Justice to indict Woodrow Wilson and Newton T. Baker, ex-President and ex-Secretary of War respectively, although quite obviously the crime charged against the defendants was equally chargeable against the heads of the administration. Col. Stimson, although a Republican, said that the indictment was obviously an attempt on the part of the present administration to transform a political difference of opinion into a criminal prosecution. He insisted that were the indictment of Mr. Crowell and his associates upheld no President would ever be free to exercise his function as Commander-in-Chief of the Army and Navy. If confronted with the emergency of war and the imperative necessity of prompt action, the executive would be compelled to appeal to Congress for specific authority for his every important act, to await debates and enactment, or else to act with the knowledge that a criminal indictment would hang over his head.

Ex-Congressman McCullough said that the crime consisted in the deceit of the responsible officers of the government, misrepresentation of material facts, resort to coercion, and finally the control and domination of the whole construction activities of the government during the war. The waste and delay due to the methods adopted might have been vitally contended had the nation been forced to exert its every effort to win the war.

Ford Muscle Shoals Offer Still Stands

Appeal to Farmers in Attack on Sale of Gorgas Steam Plant—Weeks Replies

In an attack on the Secretary of War for the sale of the Gorgas steam plant to the Alabama Power Co., Henry Ford stated that his offer to buy the Muscle Shoals development still stands. He accused the Secretary of War of favoring interests who opposed the use of Muscle Shoals for the manufacture of fertilizer when he sold the steam plant. He said in part as follows:

"Long ago Mr. Weeks matured in his mind the plan to break up Muscle Shoals and dispose of it piecemeal. When he sold the steam plant at Gorgas he pulled the first stitch in unraveling the greatest prospect ever held out to the American farmer and manufacturer.

"The next steps are so plain that a child can see them. It only remains to sell the gigantic nitrate plant No. 1, and then nitrate plant No. 2, and finally the Wilson Dam itself, and that is the end of Muscle Shoals as a possible demonstration of the cheapness with which power and fertilizer can be produced.

"The Ford Motor Co. never has needed Muscle Shoals. We have water-power sufficient for all our purposes. The only thing I could do at Muscle Shoals which I am not able to do elsewhere would be to make fertilizer for the farmer. And that is the sole reason why John W. Weeks and scores of corporation lawyers have exerted their cunning to prevent me. The same influences that prevented a vote in the House last Spring are responsible for the sale of the Gorgas plant to prevent a vote on Gorgas."

In repeating his offer to buy the whole development Mr. Ford made a statement regarding the use of the power which he has not made before, i.e., that power would be sold to the surrounding community. He said:

"My offer is still before Congress. I shall not withdraw it. There is nothing whatever for me to explain. There is nothing that John W. Weeks can explain, though he should talk from now until he leaves public life, but I want to say this: If I get Muscle Shoals we shall run power lines 200 miles in every direction from Muscle Shoals. We have been working and have learned how to send power long distances without losses by leakage. I say this now for the benefit of the international financiers, who, with the Alabama Power Company, have Muscle Shoals almost hopelessly in their grasp."

SECRETARY WEEKS REPLIES

In reply to Mr. Ford the Secretary of War said:

"Muscle Shoals was a development for nitrate purposes in the war, which included the construction of a large dam on the Tennessee River, and the construction of two air-fixing nitrate plants, with large quarries, and as an adjunct to these plants, in order to supply power ending the completion of the water power dam, a steam plant was erected ninety miles away on the Warrior River, known as the Gorgas plant.

Texas Plans Water-Works Course

A short course of instruction for water-works operators and engineers will be given at Waco, Texas, Jan. 21-26, 1924, covering waste water, water control, boiler room economy, filter plant operation, geology of underground waters and legal responsibilities. The course, of which this is the sixth year, is given under the auspices of the Texas Water Works Association, the Southwest Water Works Association, the Texas State Board of Health, the University of Texas, and Baylor University. Dr. W. T. Gooch, of the last named school, is director of the course.

"The total expenditure on these properties was about \$102,000,000 of which less than \$5,000,000 was spent upon this isolated and temporary steam plant. The steam plant was erected on the property of the Alabama Power Company, which reserved title to the land on agreed conditions which gave to them the right to purchase the Gorgas steam plant.

"The proposals made by Mr. Ford for the purchase of this entire equipment involved the payment by him of \$5,000,000 for the entire plant, including the above isolated and temporary steam plant. They also involved many other conditions with regard to the completion of the water power, etc. No disposal of government property can rightfully be made by any administrative officer without the approval of Congress, and I, as the responsible official in this matter, referred Mr. Ford's offer to Congress, which has so far not acted upon it.

"In the meantime the Alabama Power Company, under its rights in the old contract, notified the government that the lands must be vacated on or before Oct. 15 this year. They offered to pay \$3,500,000 for this comparatively small item of the whole equipment. The government had an option to accept this offer, which was the highest made, or to salvage this plant as second-hand machinery, and from which they could not have realized more than \$1,000,000. On the other hand, it must be borne in mind that for this single item in the entire equipment the government has secured \$3,500,000 as against the \$5,000,000 offered by Mr. Ford for the entire plant and equipment.

"At the time of the sale, in a desire not to disturb the *status quo*, the administration stated to Mr. Ford that this amount could be credited on his original offer of \$5,000,000 if it was so wished.

"Mr. Ford's declared purpose in purchasing the Muscle Shoals is the manufacture of nitrates for fertilization purposes. I have never opposed Mr. Ford's securing the use of this water power or any other equipment we have, provided he is able to give such assurance of its being devoted to this particular purpose as will satisfy Congress and properly protect the public interest. That he could ever economically make nitrates by the use of steam power is denied by every expert adviser.

"The fact that he says his offer is still open would seem to indicate that he does not regard the Gorgas steam plant as necessary to him in the carrying out of his plan to purchase and develop Muscle Shoals water power."

Frederick L. Cranford Nominated to Head A.G.C.

Resolutions opposing "outside" inspection of work, declaring against extension of public ownership of utilities, opposing changes in the Transportation Act and endorsing the objects of the National Transportation Institute, and appointment of a committee to formulate a safety policy with the National Safety Council to be reported to the next annual convention, were among outstanding accomplishments of the quarterly meeting of the Executive Board of the Associated General Contractors of America at St. Louis, Oct. 4, 5 and 6.

Frederick L. Cranford, of Frederick L. Cranford, Inc., Brooklyn, was nominated by the Board for election as president at the next annual meeting. A. S. Downey, of Seattle, Wash., one of the partners of the A. W. Quist Co., was nominated for election as vice-president at large. Other nominations to fill offices in the association, secured by referendum among the member chapters, are to be announced later.

The time and place for the next convention were referred to a committee composed of President J. W. Cowper, General Manager R. C. Marshall, Jr., H. H. Wilson, A. S. Downey, H. W. Baum, Frederick L. Cranford and Sumner Sollitt. Some date in January probably will be selected and the choice of location apparently rests between Chicago and Washington.

Tyler Field, of Cincinnati, was named to succeed Col. J. R. Wiggins, of Philadelphia, as the Association's member of the Joint Board of Jurisdictional Awards in the Building Industry, Col. Wiggins having resigned owing to pressure of private business.

The Board voted \$500 to assist the work of the Committee on Seasonal Operations. This committee, organized a few weeks ago at Atlantic City, will hold a meeting in Washington, early in November, at the Department of Commerce.

Connecticut to Spend \$15,000,000 on Roads in Next Two Years

Close to \$15,000,000 will be available during the next two years to carry on the work of the Connecticut State Highway Department, according to an estimate made public recently by the Department. This sum includes direct appropriations from the state and fees which the motor vehicle department receives from registrations, licenses and fines, in addition to the state tax on gasoline. The law requires that all fees from the motor vehicle department be used for the reconstruction and maintenance of trunk line highways.

The amount appropriated by the General Assembly for the highway department for the current two-year fiscal period aggregates \$4,200,000. The remaining \$10,000,000 it is estimated, will be received through the motor vehicle department.

Heretofore, receipts from the gasoline tax have been turned into the State Treasury direct by the motor vehicle department, but the recent session of the General Assembly, however, directed that this money be devoted exclusively to the betterment of the state's roads. It is estimated that the gasoline tax will produce \$2,000,000 in revenue during the next two years.

Work's Friends Justify Davis' Removal

Again Charge Evils of Reclamation to Engineering Control—"Business Administration" Needed

A new flare-up in the controversy over the removal of A. P. Davis, as Director of the Reclamation Service, has followed the publication of articles in the Washington *Herald* attacking the Secretary of the Interior for his course in that connection, and in particular revealing the fact that on Aug. 17 an executive order was signed by President Coolidge only a day or two after he came to Washington as president exempting Director David Davis from the regulations of the Civil Service Act. This order was signed in opposition to the recommendation of the Civil Service Commission and was kept secret until the *Herald* uncovered it.

This has had the effect of stimulating friends of Secretary Work to take a more active stand in his defense. In substance this is what they contend:

"The full responsibility of making reclamation a decided success rests upon the Secretary of the Interior, a situation very distinct from that of a technical bureau having an organic act of its own. Secretary Work had been advised from so many quarters and from such reliable sources that the agricultural and business problems of the service were not being met, that he was convinced a radical change in policy had to be put into immediate effect if the service were to be saved from collapse. He had abundant proof that most of the projects were in a bad way. He realized that Director Davis could not be in full sympathy and could not give the maximum of co-operation in putting into effect policies substantially different from his own. Moreover Secretary Work had learned that a substantial number of those on projects had been antagonized to the point by Director Davis where all hope was gone of inducing them to pool together with him.

EMPLOYMENT OF ENGINEERS

"In his zeal to show the capacity of the engineering professions, Director Davis had carried the employment of engineers to a ridiculous extreme. Every important post in the service was held by an engineer as well as many of the minor positions. Even the ditch-riders were engineers. The business problems and the solution of the intricate questions of a non-engineering character long had been neglected. The reclamation projects had reached a point where they were experiencing the full effect of that neglect.

"There was no intention on the part of Secretary Work, however, to disparage the engineering work that had been done, under Director Davis' direction. He was particularly anxious that reclamation continue to have the advantage of Mr. Davis' engineering ability and knowledge of its engineering problems. For that reason, he tendered him the position of consulting engineer.

"When the matter of change of policy was taken up with Director Davis by Secretary Work, the entire conversation was an amicable one. Mr. Davis even remarked that there would be less trouble getting rid of him than was

Latin-American Road Engineers May Visit U. S.

Before calling the Pan-American Road Congress, authorized at the Santiago meeting of the Pan American Union, it would be desirable, in the opinion of some of those interested in the matter, to bring to the United States a road building engineer from each of the Latin-American countries. This was developed at a conference at the Department of Commerce October 5, attended by Assistant Secretary of Commerce Drake; Director General Rowe of the Pan American Union; Secretary General Sherwell, of the Inter American High Commission; Thomas H. McDonald, Chief of the Bureau of Public Roads; Pike Johnson, president of the National Automobile Chamber of Commerce, and Eugene S. Gregg, chief of the division of Transportation and Communication, Department of Commerce.

Since the motor vehicle industry was the only outside activity represented at this conference, a further meeting is to be held early in November at which it is expected others concerned will be present.

The thought was expressed that impetus would be given the congress idea in the various countries, were their principal engineers dealing with highway matters brought to the United States and acquainted with the progress of highway work here. They then would be in a better position to organize the participation of their respective countries in a congress which would be held at a later date, probably in some Latin-American city.

the case with Dr. Newell. A second conference took place over the form the resignation should take. Secretary Work had objected to the featuring of the fact that the resignation was tendered at his request. He felt if they were to continue to work hand-in-hand in the interest of the service, a better way of phrasing the letter could be devised. This conversation apparently was on the same friendly basis as the former one, but shortly thereafter he seemed to have developed a brainstorm which led to the final stormy interview with Secretary Work.

"The engineering end of reclamation work is not being neglected. F. E. Weymouth, whose ability is universally admitted, now is chief engineer in fact as well as in name. There will be no interference with his free exercise of authority over engineering matters.

"It is no more necessary to have an engineer in charge of all reclamation activities than it is necessary to have a surveyor as the Commissioner of the General Land Office. The chief activity of the Bureau of Indian Affairs is the conduct of schools, yet it is not regarded as essential that only school teachers be eligible to the post of commissioner.

"The much discussed executive order of Aug. 17 is simply a presidential appointment to harmonize the appointments of D. W. Davis with the appointments of his predecessors. The activities of the National Civil Service Reform League smacks of first aid for the Democratic Party. All of its representatives who have called on Dr. Work have admitted affiliation with that party. A. P. Davis was not killed. He committed suicide."

Secretary Hoover Calls Super-Power Conference

The New England and Middle Atlantic States to Co-operate — Should Develop St. Lawrence Power

At a conference of the chairmen of the various public service commissions of the New England and Middle Atlantic States, and the Secretary of Commerce held in New York City on Oct. 13, the Secretary said that the conference was called for a preliminary discussion of the co-operative steps which federal and state authorities should take to promote what is called the super-power development in the New England and the Middle Atlantic States; that the conference was not conceived with the idea of putting more government into business, but to stimulate the public authorities and industries toward co-operation in the development of a great service to the public. The Secretary said that engineering science has brought us to the threshold of a new era in the development of electric power. This new stage in progress is due to the perfection of high voltage transmission over long distances and the more perfect mechanical developments in generation of power whereby we can now undertake to develop the cheaper sources of power farther afield, such as the St. Lawrence River, and the cheaper generation from coal through larger and more favorably placed generation plants.

THREE PROBLEMS

In summing up his remarks Mr. Hoover said that there were three outstanding problems which called for solution before a great super-power system could be set up in the New England and Middle Atlantic States. These problems were (1) The legal relation such as the inhibitions against the import or export of power across the boundaries of certain states; (2) the engineering features such as the changes in frequencies necessary to make such a free flow of power possible; and (3) the promotion of co-operation between the federal government and the states over the development of interstate power or power on navigable streams and over the means of developing the St. Lawrence River, which power Mr. Hoover thinks should be developed and poured into the common pool.

After the delegates to the conference had expressed their general sympathy with the aims of the conference and their willingness to co-operate with Mr. Hoover, he proposed that a second conference be called in about a month or six weeks at which time the public utilities and chambers of commerce throughout the territory should be asked to send representatives. In the meantime, in order that the next conference might be in a position to take more definite action, the Secretary stated that he would, through conference with the various members, prepare a program and appoint sub-committees to handle the various questions; that his office would send out the program to the members of the conference for such additions or changes as they thought desirable in order that much of the routine might be cleared away before the conference met. Mr. Hoover hopes these conferences will arouse public interest in super-power systems.

Public Health Association Holds Annual Meeting

Fifty-Second Session Well Attended—
Nine Technical Sections Convene—
Dr. Park New President

Engineering News-Record Staff Report

A large attendance and a well ordered program were features of the fifty-second annual meeting of the American Public Health Association at Boston, Oct. 8-11. Besides the two general meetings on Monday and Wednesday evenings, the nine technical sections held from one to three meetings each. In general, the afternoons were left free for visits of inspection to sanitary engineering services and works in and about Boston. The Sanitary Engineering Section, for instance, devoted one afternoon to a trip to plants for the treatment of paper mill and tannery wastes on the Neponset River, and another afternoon to a visit to the old and new sewage-works of Worcester, automobiles having been provided for the party in each case.

The newly chosen president of the association is Dr. William H. Park, of the Health Department of New York City, and the first vice-president is Dr. F. H. Mahoney, health officer of Boston. The new chairman of the Sanitary Engineering Section is H. A. Whittaker, director, Division of Sanitation, Minnesota State Board of Health, Minneapolis, and the new vice-chairman is Langdon Pearse, sanitary engineer of the Sanitary District of Chicago. G. W. Simonds, Jr., director of the Bureau of Sanitary Engineering of the Florida State Board of Health, Jacksonville, Fla., continues to serve as secretary of this section.

Committee Reports—The Committee on Air, Dr. George A. Soper, New York City, chairman, secured the general approval of the section subject to availability of funds and authorization of the governing authority of the association, for the preparation of a comprehensive report, estimated to run about 150 pp., dealing with the air both inside and outside of buildings, including garbage- and sewage-works and other plants that may disseminate offensive odors. The report of the Committee on Mosquito Control, together with discussions from various viewpoints, reviewed progress of work in this field. Emphasis was laid on the need of better machinery for digging the 10-in. trenches common to meadow drainage for mosquito control. It was stated that a ditcher is needed that is self-contained and that will be able to break up the sod so that it will not be washed about over hay lands at high water. The Committee on Bathing Places, through George W. Simonds, Jr., chairman, reported that several states have already adopted the tentative standards set up by the committee. The committee strongly believes that methods of analysis suitable for potable water are not well suited for the control of bathing places, but advises for the present the continued use of the A.P.H.A. standard of water analysis.

Garbage and Refuse Disposal—M. N. Baker, chairman of the committee on garbage collection and disposal, laid stress on the unsatisfactory condition of garbage disposal, which he considered to be the least satisfactory of any of the municipal public services

today. This he attributed largely to the fact that garbage and refuse disposal is not generally regarded by city authorities as an engineering matter. A paper on the Becari system of garbage disposal was presented by J. Waldo Smith, consulting engineer, Board of Water Supply, New York City, who is also president of the American Becari Corp. Information was presented regarding several Becari plants in Italy (see *Engineering News-Record* of Feb. 15, p. 324). Briefly, this is a fermentation system of garbage disposal, the garbage being deposited in cells of about 25 cu. yd. capacity, four cells comprising a unit. In the colder parts of the United States it would be necessary to provide not only a cover for the cells but also a roof over the cells as a whole. A Becari installation of two units is being installed at Scarsdale, N. Y., and will be in operation the latter part of this month. In discussing this paper, George W. Fuller remarked that he had recently seen the Becari plant at Florence, Italy, which plant seemed to be operating satisfactorily. Mr. Fuller stated that the process seemed to him to be a most interesting development of a rotting process similar to that applied to barnyard manure. He is somewhat skeptical as to the amount of oxidation that would result from the entrance of air through the openings provided for that purpose. The refuse being treated at Florence seemed to be mixed material, including manure. Apparently the process at least for some days was due to anaerobic action. Besides taking part in this discussion, Mr. Fuller presented a paper on "European Observations on Refuse Disposal," an abstract of which will appear in a later issue.

For the Committee on Water Supply and Purification, George W. Fuller presented a general survey of the field, in the course of which he called attention to new filters or extensions to old filters under construction at Philadelphia, Baltimore, Richmond, Grand Rapids, Minneapolis, Milwaukee, Detroit, Cleveland, Buffalo, Montreal and numerous smaller cities. Because "superchlorination seems likely to come into wider use," said Mr. Fuller, "especially for unfiltered supplies and for supplies which are filtered under conditions permitting plankton growths to exert an influence on the water as it reaches the consumer, it is well to bear in mind that the excess of chlorine may be removed by reducing agents, such as sulphur dioxide, thiosulphate, etc."

Sewage Sludge Committee—The report of the sludge committee, by Langdon Pearse, Chicago, reviewed progress and practice in sludge utilization at Milwaukee, Chicago, and elsewhere. The Milwaukee Sewerage Commission reports that T. Chalkley Hatton, chief engineer, has appointed a fellow to the agricultural college of the University of Wisconsin, who is devoting his entire time to the use of sludge in agriculture. The value of activated-sludge in comparison with various mixes of commercial fertilizers is being studied on a number of different crops at various experimental farms, on golf greens, etc., in Wisconsin. The co-operation of the National Fertilizer Association in the study of this general subject has been obtained. The Sanitary District of Chicago, stated Mr. Pearse, has interested a number of agricultural ex-

periment stations in making tests of the fertilizing value of sludge. Work is now under way on cotton in Mississippi and on garden plants at the University of Illinois. From Baltimore, it is reported by Milton J. Ruark, division engineer of sewers, that the entire sludge production for the year 1922, which was about 5,400 tons on a dry basis, was either dried by heat in a contractor's plant or on drying beds, air drying on the beds being used exclusively the latter part of the year. The farmers take away all the air dried sludge but for more than a year no charge for it has been made by the city. In co-operation with the Agricultural Experiment Station of Baltimore nine acres of land have been laid out in six sections of one-half acres each, and each section divided into six plots of one-fourth acre each, for comparative studies of liquid digested sludge, air dried sand bed sludge, commercial fertilizer, commercial fertilizer and dry sludge and manure, while as a control one plot has been given no treatment. During the year 1922 the preparation of air dried sludge cost 66¢ per ton. Sludge utilization at Rochester, N. Y., and Houston, Texas, was also reported by Mr. Pearse.

A review of "Thirty Years of Sewage Treatment at Worcester, Mass.," was presented by Roy S. Lanphear, supervising chemist of the Sewer Department. Chemical precipitation has been used since March, 1890, supplemented by slow sand filters since 1893, the acreage of the latter having finally been extended to about seventy-five. Imhoff tanks and sprinkling filters are now under construction.

Under the title "Observations on the Pollution and Natural Purification of the Ohio and Illinois Rivers," W. H. Frost, surgeon, U. S. Public Health Service, Baltimore, Md., reviewed studies begun in 1913, interrupted in 1917 by the war, and again carried on during the past two years. Besides their local application the object of the studies "has been to investigate the possibility of establishing closer, more general and more fundamental correlations between the degree of pollution in streams as shown by laboratory tests and such obvious contributing factors as are readily determinable by field surveys."

Treasury Water Standards—The standards for water supply to trains and steamships in interstate commerce, commonly known as the Treasury Standards, were discussed at length by representatives of the United States Public Health Service and members of the Sanitary Engineering Section. George W. Fuller raised a question as to whether there would be taken into account, in addition to the proposed B. Coli index, all the antecedents of the supply. He suggested setting up a standard higher than the present one with the understanding or hope that it might be attained within the next ten years. He also noted that abroad standards are set up with the understanding that exceptions will be made for certain places to suit local conditions.

Speaking for the Field Survey Subcommittee of the Public Health Service's Advisory Committee on Water Standards, Prof. George C. Whipple said that much time had been spent trying to meet the ideas of some to the

effect that a scoring system for water supply should be devised. This has been given up. The committee is now considering five classes or ratings of water supply: Excellent, good, fair, poor and bad. Professor Whipple stated that his idea is that no water supply should be approved unless a sanitary survey shows it to be satisfactory. If the supply passes the sanitary survey, then bacterial and chemical data should be considered and the supply accepted or rejected after consideration of all three classes of evidence. There should be for every supply either satisfactory means of purification or else purification should not be needed. No supply should be approved if the sanitary survey shows any one of a number of major deficiencies, including such things as interconnection with possible polluted supplies, overloaded filters or by-passes around filters.

A progress report was made for the sub-committee on Chemical and Physical Standards, the report being presented by Jack Hinman of Iowa in the absence of Edward Bartow, chairman, who holds that satisfactory supply should be clear, colorless, odorless, tasteless, have certain specified chemical limitations, particularly as to lead, zinc and magnesium. Dr. H. A. McLaughlin of the Public Health Service expressed the opinion that many of the chemical and physical standards proposed by the committee were beyond the scope of the Treasury Standards.

In the course of the discussion Harry Jordan, sanitary engineer, Indianapolis Water Co., urged that there was danger of the new standards being put so high as to embarrass many water-works plants and Abel Wolman reviewed objections along this line made by representatives of a number of water-works. Mr. Wolman's conclusions seem to be that a very considerable percentage of the water-works of this country could readily meet the proposed new standards. Dr. William H. Park of New York City expressed the belief that in the New York City supply there was present a large margin of safety—this supply being one of these that have not been complying with the existing or Treasury Standards. Dr. M. J. Rosenau of Harvard University called attention to the fact that the old chemical standards as well as the present bacterial standards are based only on index of pollution.

Dr. McLaughlin said that it is hard to get down in words any directions for correlating bacterial and field surveys, but expressed the belief that as a matter of administration there would be no difficulty in such correlation.

Pacific Highway Links Completed

Good roads enthusiasts of the state of Washington will celebrate on Oct. 23-25 at Olympia completion and official opening of the last links in a 700-mile paved highway which stretches from British Columbia to the California-Oregon state line. When California completes a 114-mile gap, the Pacific Highway will be hard-surfaced from Vancouver, B. C. to Tia Juana, Mexico, and will be the longest international paved road in the world. Officials and good roads advocates from British Columbia, Oregon and Washington will take part in the exercises.

Random Lines

We Nominate Dr. Work for Dean of the College

Young men complain that the learned professions are overcrowded. We shall endeavor to earn their gratitude by suggesting to them a new avenue for their energies.

We believe there is a large field and rich rewards for the college graduate who will take up the profession of *political engineering*, which will lead to the universities conferring the degree of Bachelor and Master and result in qualified graduates only being retained as the advisers of political candidates. We must do in politics what we have done in architecture, mechanics, chemistry, all the various activities of life, to the advantage of all concerned. Our present methods are inefficient, wasteful, unscientific; we would put the business in the hands of experts, men trained in their profession, and save the candidates money and the people much trouble.—From the political correspondence column of the New York World, "The Looker on in Washington."

Concrete vs. Masonry; An International Analogy

From the speech of David Lloyd George, at Montreal.

"I have just come from your great neighbor. Their problem is a different one from ours. Their problem is to weld all those races into one common pattern. Their business is to do what you see those great machines do when they are making concrete—crush the rocks into the same size, the same pattern, weld it together by some substance that attaches and makes cohesion. There you have got to make the concrete, attach it by a common nationhood so as to make one solid nation of an infinite variety of types. That is the problem of the United States.

"Our problem is a problem of hewing rocks of granite or marble out of different quarries; of fashioning them, shaping them, putting them into the building—each separate block contributing its strength to the building, each contributing its color, its beauty, so that the whole will be a fabric of infinite strength and exquisite beauty—that is the British Empire."

Philadelphia Authorizes Huge Municipal Loan

People Will Vote November 6 on Bill Providing for Expenditure by City of \$71,000,000

At a recent meeting of the Philadelphia City Council a municipal loan of \$71,000,000 was approved to be submitted to vote of the people at the election on Nov. 6. The loan is provided in two bills, one for a loan of \$3,000,000 to be made in 15-year bonds to cover short-life works, and the other for \$68,000,000 to be made in 50-year bonds and to provide for works of permanent character. Items provided in the fifteen year loan are: Street and road paving and repaving, \$2,400,000; extension of police signal system, etc., \$440,000; refund of money appropriated from current funds for improvement to the Institution for the Feeble Minded, \$160,000.

Chief among municipal improvements provided for by the 50-year loan are the construction of the first step in the recently approved high-speed transit system for the city, and the completion of the Delaware River Bridge. The complete list of items in the loan follows:

Completion of Delaware River Bridge,	\$5,623,000
Broad street subway, with Ridge Avenue, Eighth, Walnut, and Chestnut St. subway, and Woodland Ave. elevated,	15,000,000
Surface car subway in Chestnut St., connecting to Delaware River Bridge,	10,000,000
Surface car line from Frankford "L" terminal,	750,000
Harbor improvements,	2,000,000
Sewage disposal plant,	9,000,000
Water supply system,	6,000,000
Street improvements,	500,000
Free library buildings,	1,000,000
Construction of sewers,	3,300,000
Construction of city bridges,	500,000
Construction of City Hall annex,	2,000,000
High-pressure fire service extensions,	200,000
Art museum construction,	2,000,000
Street damages, etc.,	5,077,000

The bills for these loans had been passed by City Council at a previous meeting and submitted for action of the Mayor. The Mayor returned them to Council unsigned, stating that he considered the provisions for city transit to be unduly favorable to the Philadelphia Rapid Transit Company, and that he did not approve of the provisions made for the City Hall Annex because another site is already owned by the city on which it had been contemplated to erect such a structure. The bills were repassed by City Council without action by the Mayor and were ordered to be submitted to vote of the people at the general election on November 6, 1923.

Sir Henry Maybury Invited to U. S. by Highway Officials

Sir Henry Maybury, the British road authority, has been invited by the American Association of State Highway Officials, the Highway Education Board, the American Road Builders' Association, and the Highway Research Council, to come to the United States to discuss plans for the proposed English-speaking road congress, which it is hoped to hold in the United States in 1926. Some of those who attended the Congress in Seville this year were convinced that more headway could be made at an assemblage of that character when a common language can be used.

Dean Cooley Resigns as Federation Head

Ill Health Cause—Executive Board Authorizes Action in Dismissal of Former Reclamation Head

Announcement of the resignation as president of the Federation of Dean Mortimer E. Cooley, authorization of a protest letter to be sent Secretary Work for his dismissal of A. P. Davis from the Reclamation Service, and reports and action upon licensing and government reorganization, were features of the session of the executive board of American Engineering Council of the Federated American Engineering Societies held at Rochester, N. Y., Oct. 11. Dean Cooley is retiring because of ill health. He has been granted a leave of absence from the University of Michigan for the second half of the 1923-1924 academic year. As his term as president of the Federation does not expire for another year it is probable that action will be taken whereby the beginning of the two-year tenure of the new president will begin in 1924, thereby making it unnecessary to select a president to fill the unexpired term.

REPORT ON DAVIS DISMISSAL

Chief among committee reports was that of the Committee on Public Affairs, details of which outlined herein were authorized. It recommended that "a strong and dignified letter be addressed to Secretary Work commenting upon his letter of Aug. 14" which should bring out the following points:

1. That "an engineer and business man are not necessarily two distinct individuals, that a man with engineering training can be an excellent business man, and that, particularly in operations where engineering plays a large part, the executive or business man is more capable of filling the position if he has an engineering training."

2. That Secretary Work is "wrong in assuming that as soon as a project is finished, or supposed to be finished, its engineering aspect ends, and that then it is purely a business proposition." The letter should also state, the committee recommended, that reclamation is an ever continuing engineering matter.

3. That objection should be registered against the dismissal of any engineer or technical employee occupying "an important and responsible position" arbitrarily and "without a hearing at which charges may be brought against him and which he may have an opportunity of refuting."

In addition to this letter the committee recommended that a congressional investigation be made of the Davis-Davis matter and that it would probably be advisable for all constituent members of the Federation to acquaint members of congress in their respective communities with the underlying facts. The committee refrained from approving or disapproving the fact-finding commission which Secretary Work has appointed to get reclamation facts, inasmuch as members might have to appear as witnesses before the Work commission, or that the dismissal of Mr. Davis might not be considered at all by the commission.

In connection with the Davis matter, the Public Affairs Committee which had met a few days previous to its report

in joint session with a special committee from the American Society of Civil Engineers, reported upon information given on reclamation and irrigation matters by Frank C. Wight, managing editor of *Engineering News-Record*, who explained the scope and broad content of the series of articles which this journal starts next week on reclamation.

The committee on Public Affairs also recommended that no action be taken at this time relative to the trial of so-called war-fraud contractors and engineers. Discussion of action on the Public Health Service led to the conclusion that it would be inadvisable to take action, owing to the strong belief among committee members that investigation of public health was not an engineering matter.

DEPARTMENT OF PUBLIC WORKS

The Executive Board of the Council passed a resolution urging that the president of the Federation be authorized to appoint a special committee to "draft and have introduced into Congress a bill carrying into effect the portion of the reorganization plan" now before that body and prepared by the Joint Committee of the House and Senate. This action is in line with previous action on the part of certain engineering societies for the establishment of a national Department of Public Works, which should include all the engineering functions of the reorganized Department of the Interior, as contemplated in pending legislation. The Council, however, expressed regret at the delay in pushing the legislation, so put into resolution form its desire to consolidate engineering backing of a public works department.

The Publication Committee reported that wide publication had been secured in the public prints for the activities of the Federation, and that it was impossible to get advertising for the Federation's bulletin with its limited circulation.

Calvert Townley reported for the special committee on Revision of the Constitution that it was considering a simplification of the name by leaving out the word Federated, making it American Engineering Societies, and calling the American Engineering Council simply the Council of the American Engineering Societies. There was a lengthy discussion as to the possibility of considering affiliation of local societies at a reduced cost per capita through state representation at the January meeting of the Council, but it was finally decided that a more deliberate course would be preferable.

LICENSING OF ENGINEERS

The report of the committee on Registration of Engineers occasioned a long debate. The model law drawn up by the committee, of which Gardner S. Williams is chairman, and submitted at the St. Paul meeting, is still being circulated for suggestion and comment. The mining and the chemical engineers object to any model law, urging that even if the expressed attitude of the F.A.E.S. is against registration the attempt to insure sanity and uniformity in states where it is inevitable by offering a law which is least objectionable will be misunderstood.

The next meeting of the Council of the Federation is set for Jan. 10 and 11 at Washington.

Recommends Safety Provisions in Federal Activities

That safety conditions in the federal service are behind the times was stated in a letter to President Coolidge made public by the Federated American Engineering Societies, the writer being M. G. Lloyd, chief of the Safety Section of the U. S. Bureau of Standards, and acting president of the American Society of Safety Engineers. The Executive Board of the Engineering Foundation, of which Mr. Lloyd is a member, has sanctioned a program for safety provisions in the activities of the government. Mr. Lloyd in calling attention to the recent disaster at the Bureau of Standards states that the American Society of Safety Engineers took cognizance two years ago of the lack of safety provisions and passed a resolution at that time. Also, a resolution was recently passed by the American Engineering Council of the Federated American Engineering Societies. Mr. Lloyd asks President Coolidge to include in his next message to Congress a recommendation for legislation which will establish in the federal departments adequate accident-prevention measures such as have been already recommended by the Congressional Joint Committee on Reclassification.

Engineers to Aid Seattle Chamber

The Seattle Chamber of Commerce has appointed a board of engineers to co-operate with and advise the industrial committee of the chamber, and compile information relative to the expansion of industry in the city. James E. Blackwell, city engineer of Seattle, is chairman of the board, and other members include: A. M. Young, structural engineer; E. L. Webber, consulting engineer; George Jamme, mining engineer; A. A. Miller, electrical engineer; A. L. Knisely, chemical engineer; and Joseph Jacobs, consulting engineer.

An important activity of the board will be to compile information relative to industries for which Seattle offers particular advantages. Heretofore, this information has been compiled at intervals by specialists hired by the chamber, and such information, while satisfactory at the time, soon became out of date. The new board will be at the service of the committee to provide any character of industrial or engineering information required.

Iowa Water Works Men to Meet

The Iowa Section, American Water Works Association, will meet Oct. 21, 25 and 26 at Ames and Boone, Iowa. Nebraska, Missouri and South Dakota are included in this section. Fifteen papers, a round-table discussion, a joint session with the Ames Engineering Society and Ames Chamber of Commerce and an inspection of the water plants of Ames and Boone are scheduled. The papers will cover bacterial content, well water, geology of water supply, records, supervision, publicity, finance and fire insurance in addition to a description of four Iowa supplies. A sewage disposal conference of Iowa operators Oct. 22 and 23 will precede the water-works meeting.

St. Louis Zoning Ordinance Held Invalid by State Court

The Supreme Court of Missouri in a four-to-three decision handed down on Oct. 6 held that the St. Louis zoning ordinance is invalid on the ground that it is not an authorized exercise of the police powers granted the city by the state. The main opinion, written by Judge Robert F. Walker, was in the case of the Penrose Investment Co., which sued to compel James N. McKelvey, director of public safety, to issue a permit for the erection of an ice-making plant. Other suits included in the decision were brought by parties who had been refused permits for a junk shop and for an apartment house, the latter to face on Forest Park. If the city fails to get a re-hearing it will appeal the suit to the United States Supreme Court.

editor of *Engineering News-Record*, on "The Imperfect Art of Engineering."

The Iowa Section of the American Water Works Association will have its annual meeting Oct. 24-26 at Ames and Boone, Iowa, with meetings at Iowa State College at Ames and inspection of the water works at the two towns. Members of other state sections will be made welcome.

The Colorado Scientific Society had as a recent speaker D. W. Brunton, chairman of the board of consulting engineers for the Moffat tunnel, who spoke on the problems contemplated or likely to arise in the boring of the tunnel. He also pointed out that when the Moffat tunnel is completed, if the Denver & Rio Grande Western R.R. will build the "Dotsero cutoff," about 42 miles of track, the distance from Denver to Salt Lake can be shortened by 174 miles.

M. F. LONGWILL and J. J. BAXTER, division engineers of the Wabash R.R., have been appointed assistant chief engineers in charge of the eastern and western districts respectively.

S. W. FREESE, associated with John B. Hawley, Ft. Worth, Tex., a hydraulic engineer, has been given a year's leave of absence to take a master's degree in engineering at Trinity College, Cambridge University, England. Mr. Freese is a graduate in civil engineering from Massachusetts Institute of Technology and had previously attended Southern Methodist University at Dallas.

GEORGE O. BUTLER, C. A. BARNETT, and ALEX O. TAYLOR have formed a partnership, known as Butler, Barnett & Taylor, in West Palm Beach, Fla., for the practice of engineering. All three were recently on the W. J. Connors Highway as chief engineer and division engineers, respectively.

W. F. HUPP, Massena, N. Y., formerly assistant superintendent on highway construction for the Shepherd Construction Co., has accepted a similar position with the Henry P. Burgard Co., Buffalo, N. Y.

LEWIS BERRY, Herington, Kan., has severed his connection with the Moreno-Burkham Construction Co. of St. Louis to become filtration plant superintendent with Burt & Tripp Construction Co.

H. S. ANDREWS, formerly bridge designer for the Long Island R.R. and residing at Jamaica, N. Y., has been appointed commissioner of public works at Fulton, N. Y.

G. F. HATCH, formerly assistant engineer of the city of Portland, Maine, has been made assistant engineer of the Pitometer Co., New York City, for work on water-waste surveys.

Engineering Societies

Calendar

Annual Meetings

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York; Fall Meeting, Richmond, Va., Oct. 17-20.

AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS, St. Petersburg, Fla.; Annual Convention, Atlanta, Ga., Nov. 12-16.

CITY MANAGERS ASSOCIATION, Lawrence, Kansas; Annual Meeting, Washington, D. C., Nov. 13-15.

AMERICAN ROADBUILDERS' ASSOCIATION, New York City; Annual Convention, Chicago, Jan. 14-18.

AMERICAN CONCRETE INSTITUTE, Detroit, Mich. Annual meeting (20th anniversary), Chicago, Ill., Feb. 25-28, 1924.

Personal Notes

L. F. SCOTT, who is now assistant highway engineer with the U. S. bureau of public roads with headquarters at Chicago, was formerly division engineer with the Kansas Highway Commission at Fort Scott, Kan.

D. D. MICKEY has resigned as resident engineer of federal-aid projects in Linn County, Kan., and has entered the employ of the U. S. Bureau of public roads with headquarters at Omaha, Neb.

A. V. MILLAR, professor of engineering at the University of Wisconsin, Madison, has been appointed assistant dean of the college of engineering, University of Wisconsin.

ENAR G. ALMQUIST, lieutenant of the Royal Corps of Engineers of Sweden, is making a tour of the United States with a view to gaining practical experience about engineering construction in this country, particularly with reference to road and bridge construction. He has spent several weeks in Philadelphia working as carpenter's helper on the construction of the anchorages of the Delaware River Bridge.

W. A. MACLEAN, deputy minister of highways for Ontario, has resigned and is succeeded by S. L. SQUIRE, who has been prominent in connection with the good roads movement.

LYDD ALDRICH, who had charge of the concrete test highway at Pittsburg, Calif., has opened an office as consulting highway engineer in Los Angeles.

HORNADAY CONSTRUCTION CO., municipal contractors and engineers, Memphis, Tenn., announce a local change of address from 1261 Central Ave. to 388 Shrine Bldg., Memphis.

R. H. HOWARD, chief engineer of maintenance-of-way, Wabash R.R., has been appointed chief engineer, succeeding A. O. Cunningham, appointed consulting engineer. The two former positions have been consolidated.

Obituary

HAROLD W. YOUNG, 36 years of age, assistant engineer on the Southern Pacific R.R. Natron cutoff project near Klamath Falls, Ore., came in from the project Oct. 9 and later was found dead in a hotel in Klamath Falls, shot through the head, with every indication of suicide.

J. H. PATTON, assistant division engineer of the Union Pacific R.R., with headquarters at Salt Lake City, Utah, was killed Oct. 11 near Medicine Bow, Wyo. With a companion he was riding on a "speeder" making an inspection. A freight train caught them, crushing the car, killing Mr. Patton and seriously injuring G. R. McDougal, his assistant. Mr. Patton was 24 years of age.

RALPH PETERS, president of the Long Island R.R. since 1905, died suddenly of heart disease Oct. 9 at his home at Garden City, L. I. On Nov. 19 he would have reached his 70th birthday and retired. Mr. Peters was born in Atlanta, Ga., a son of Richard Peters, pioneer railroad builder, and was a graduate of the University of Georgia, class of 1872.

The California Section of the American Water Works Association will hold its fourth annual convention in Fresno, Oct. 25-27. Interesting features will be an automobile trip to the Kerckhoff dam and power house of the San Joaquin Light & Power Corp., and, on invitation of the Bureau of Sanitary Engineering of the State Board of Health, a visit of inspection to several sewage-disposal plants in the vicinity of Fresno.

The Engineers' Club of Trenton, N. J., at its meeting Oct. 11 enjoyed an illustrated talk on "The New York and New Jersey Vehicular Tunnel" by Colonel Frederick A. Snyder, assistant engineer of construction on the tunnel.

The Texas Section of the American Society of Civil Engineers recently held its fall meeting, electing officers as follows: President, H. A. McKenzie, of the McKenzie Construction Co., San Antonio; vice-presidents: John A. Morris, State Board of Water Engineers, Austin, and J. C. McVea, city engineer, Houston; and secretary-treasurer, E. N. Noyes, Myers & Noyes, construction engineers, Dallas.

Harvard Engineering Society, Undergraduate Section, was addressed Oct. 13 by Frank C. Wight, managing

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Japan Places Large Orders for American Lumber

At least a full month earlier than had been expected by Northwest lumbermen, Japan has placed initial orders for 80,000,000 ft. of North Pacific Coast lumber for reconstruction purposes. The order is largely for squares and "baby" squares, indicating that Japanese saw mills are not all out of commission. A quantity of the order was for lumber of ordinary mill stock sizes which, until next April, can be sent into Japan duty free under an emergency tariff suspension rule. The effect of the Japanese orders will undoubtedly be to strengthen a market already strong and to stimulate production by the mills. Labor supply is reported adequate for the increasing demands and at present there is no log shortage.

Report of the Pacific Northwest Lumber Inspection Bureau for the first six months of 1923 shows that cargo shipments of lumber from Pacific Northwest ports have exceeded those of the same period of 1922 by more than 11 per cent and have set a new record.

Electrical Equipment Orders for Japan Exceed \$1,000,000

The Westinghouse Electric International Co. has received orders for electrical apparatus to be used in reconstruction work in Japan totaling well over \$1,000,000. Other orders are in course of negotiation which will bring the total amount to approximately \$2,000,000. It is understood that the power plants in the quake zone were not seriously damaged but that the distribution systems were practically destroyed.

Portland Cement Association Sends Investigator to Japan

Homer M. Hadley, district engineer in charge of the Seattle office of the Portland Cement Association, sailed Oct. 5 for Japan to investigate results of the earthquake on Sept. 1 upon modern structures, particularly those consisting largely of reinforced concrete. Mr. Hadley will probably be absent three months at least, although it is expected he will be able to cable a condensed preliminary report soon after his arrival.

Mr. Hadley's structural experience was gained with a number of the foremost Pacific Coast engineering firms.

American Motor Trucks Shipped to Aid Japanese Restoration

Shortly after wire communications had been established, following the Japanese earthquake, cabled instructions were received in this country for the shipment of American motor trucks. The first consignment of Pierce-Arrow machines has already been made and a second shipment is about to leave.

Asphalt Simplification Effective Jan. 1

Commerce Department Announces Endorsement of 10 Varieties by Consumers and Producers to Reduce Waste

After January 1, 1924, "Too many asphalt grades" no longer will be the complaint of public highway officials, engineers, contractors, and producers, the Department of Commerce having announced that upon that date the recommendations adopted at its recent asphalt paying conference will become effective and asphalt grades for use in

(I) For construction of Sheet Asphalt, Asphaltic Concrete, and Asphalt Macadam Pavements, and also for Surface Treatment.

Penetration Limits		
25 to 30	50 to 60	100 to 120
30 to 40	60 to 70	120 to 150
40 to 50	85 to 100	150 to 200

(II) For Joint Filler for Various Types of Construction.

Penetration Limits	
30 — 50	60 — 70
50 — 60	85 — 100

The first is used primarily for brick pavements, and does not require the admixture of sand, whereas the latter three which are identical with three of the grades adopted for asphalt pavement construction, are those which would ordinarily be used in admixture with sand to produce an asphaltic grout.

(III) In adopting these limits, it is understood that the producer will furnish asphalt with penetration equal to the mid-point in each range, a plus and minus tolerance from that mid-point being acceptable to all parties, but in no case shall the deviation exceed the limits of the grade specified.

the construction of sheet asphalt, asphaltic concrete, asphalt macadam, and surface-treated pavements will be reduced from 88 to 9. The number of asphalt grades used as joint filler in the construction of brick and block pavements and various other types has likewise been reduced from 14 to 4 [of which 3 are included in the foregoing 9 grades for roads and streets, bringing the total of approved grades for all paving purposes to 10].

A complete report of the conference at which the reduction in the number of asphalt varieties was adopted is in process of printing and will be published about Dec. 1 by the Department of Commerce as one of its series on "Elimination of Waste in Industry." It will be entitled "Simplified Practice Recommendation No. 4—Asphalt" and can be obtained from the Superintendent of Documents, Government Printing Office at Washington at 5c. per copy.

The endless multiplicity and non-uniformity of specifications having reached a point which demanded nationwide co-operative action on the part of engineers, contractors and producers, at the suggestion of Secretary Hoover a systematic approach to a solution was made during the spring and summer by all parties interested and a constructive

Committees Named for Road Show and Convention at Chicago

Chairmen of committees for the Good Roads Show and convention of the American Road Builders' Association, to be held in Chicago, Jan. 14-19, have been named as follows:

PUBLICITY, S. T. Henry, Allied Machinery Co. of America, New York; RECEPTION AND HOTEL, G. W. Craig, Asphalt Association, Chicago; REGISTRATION, L. S. Louer, *Engineering & Contracting*, Chicago; PROGRAM, C. S. Hill, *Engineering News-Record*, New York; ENTERTAINMENT, A. Cronkite, Universal Portland Cement Co., Chicago; BANQUET, J. F. McGurk, Camden Petroleum Co., Chicago.

All of these committees will report to the convention and show manager, Charles M. Upham, State Highway Engineer, Raleigh, N. C.

Production of Lumber, Lath and Shingles: 1922 and 1921

The Department of Commerce announces that the total production of lumber during 1922 in the United States was 31,426,922,000 ft., an increase of 16.5 per cent when compared with the cut reported for 1921, but a decrease of 9 per cent compared with the cut for 1919.

The production of lath was reported as 2,905,585,000 in 1922 and 1,970,696,000 in 1921, and the production of shingles 8,068,585,000 in 1922 and 6,843,187,000 in 1921.

Comparing the statistics for 1922 with those for 1921 the greatest changes are shown for the western states, the states in that region apparently having recovered from the severe depression of 1921.

In 1922 yellow pine contributed 36.6 per cent of the total cut for all kinds of wood, Douglas fir 21.4 per cent, and western yellow pine 6.6 per cent.

The figures for 1921 and 1922 are not strictly comparable. In 1922 the output of mills cutting under 50 M ft. each was omitted and in 1921 the cut of custom mills was omitted. The cut of neither class, however, materially affected the totals.

reduction of varieties was effected.

Nine definite penetration limits for the construction of sheet asphalt, asphaltic concrete, asphaltic macadam pavements and for surface treatment, and four penetration limits for joint filler for various other types of construction, including brick and granite block pavements, were unanimously adopted at a general conference held at the Department of Commerce on May 28, 1923, and have been officially accepted as the standard of practice by the highway engineers of 30 states, the American Society for Testing Materials, the Society for Municipal Improvements, the American Society of Civil Engineers, the United States Bureau of Public Roads, the Asphalt Association, and 5 manufacturers not members of the Asphalt Association. It was the sense of the conferees that the recommendations should become effective on all deliveries of material after Jan. 1, 1924, and that they should be subject thereafter to annual review and such revision as the industry may desire.

The accompanying table gives the penetration limits as adopted.

Advertisers Urged to Use Complete Street Address

Advertisers in newspapers and magazines are causing a great deal of trouble to the United States Post Office by failing to use a complete street address in their printed matter. In the larger cities particularly the manufacturer's name followed by the name of the town and state is not always sufficient identification for the rapid distribution of mail. Postmaster E. M. Morgan, of New York City, has just sent out a statement calling upon advertisers to help the Post Office Department by using street addresses in all of their printed literature and other advertising. In New York, according to Mr. Morgan, 80,000 pieces of mail, exclusive of those addressed to the largest and best known firms, are received at the New York post office every day without street address. The delivery of the bulk of this mail is delayed from 8 to 24 hr. and every day 10,000 pieces of mail remain undelivered for want of a complete address.

Postmaster Morgan says in part: "If advertisers do not include in their advertisements the complete address that will insure delivery of mail sent as the result of such advertisements, not only will the burden of disposing of this mail continue but the advertiser will lose the business which he is seeking by reason of delay or non-delivery of the replies."

Name Members of Japan's Reconstruction Board

The Metropolitan Reconstruction Board in Japan, which is to have charge of all reconstruction work throughout the devastated area, has been enlarged and will consist of eleven members, according to a cablegram to the U. S. Department of Commerce from the commercial attaché at Tokyo. K. Inaba, formerly chief of the Engineering Bureau of Hokkaido, has been named chief of the Land Adjustment Bureau in place of S. Miyao who was originally selected for that post. E. Ota, formerly counsellor for the government railways, has been designated chief of the Engineering Bureau in place of R. Naoki, who will serve as chief engineer. The office of executive secretary has been assigned to K. Kanai.

Business Notes

CAL CHEMICAL Co., INC., Hagerstown, Md., manufacturer of concrete accelerator and curing compound, announces the recent opening of sales offices and warehouse facilities in Chicago and New York. The Chicago office is in charge of A. S. Harrison, who is also vice-president and Chicago manager of the Minwax Co. The New York office is in charge of M. F. Cavalon, formerly New York representative of the A. T. Malméd Co. and the Hy-Test Cement Co.

GIBB INSTRUMENT Co., Bay City, Mich., manufacturer of electric welding equipment, announces the appointment of H. A. Wilson as manager of its Detroit branch, in place of F. M. Luchs, resigned. Mr. Wilson was formerly district manager in New York for A. P. Munning & Co.

Last Call for Exhibit Space at Good Roads Show

Applications for space at the Road Show to be held by the American Road Builders' Association in the Coliseum, Chicago, Jan. 14-18, 1924, are being received in even greater volume than was the case a year ago. Allotment of space will be made Nov. 1, and prospective exhibitors who wish their applications to be considered must have them in the hands of Charles M. Upham, the association's convention and show manager, not later than Oct. 27. The application blanks were sent out some time ago, but additional blanks may be obtained by writing to Mr. Upham, care of American Road Builders' Association, Raleigh, N. C.

The meeting in Chicago on Nov. 1, at which exhibit space will be allotted, will be confined to the members of the executive committee of the American Road Builders' Association, the executive committee and representatives of the Highway Industries Exhibitors' Association and the advisory committee of the Exhibitors' Committee. On account of the large number of applications and the limited space available, it has been found necessary to restrict the attendance at this meeting to the committees named above.

Equipment and Materials

Large Tackle Blocks Hand Made

For handling 68-ton plate girders on the new Straus building in Chicago, described in *Engineering News-Record* of Sept. 27, p. 523, exceptionally large tackle blocks were supplied to the contractors, the Thompson-Starrett Co., by the W. W. Patterson Co. of Pittsburgh, for use on two large guy derricks. There were two five-sheave blocks and six six-sheave blocks, which are shown in the accompanying illustration. The former weighed 623 lb each and the latter 720 lb each.

These blocks were hand-made throughout. They had shackles forged from solid 5 x 5-in. billets hammered down to 3 in. round and bolts 2 in. in diameter. The diameter of the sheave pins was 2 in. The straps were 5 x 5 in. and all plates were 3 in. thick. The edges of the plates were ground and filed to prevent cutting of the cable. The sheaves were 16 in. in diameter and were grooved for 3-in. cable.

Portable Wood Working Machine Cuts Cost of Forms

To reduce the cost of labor in making wooden forms for concreting and for other forms of millwork, including sawing, mortising, drilling and planing, the P. L. Billingsley Co., 425 Elm St., Cincinnati, Ohio, has developed the portable, electrically operated wood-working machine illustrated in the accompanying photograph. The machine, called the Flexway, is mounted on a four-wheel carriage with roller bearings and the swivel post is carried on ball bearings. The sawing head is adjustable to cut any angle up to 55 deg., a feature adapting it particularly to the cutting of jack rafters, in addition to joists, studding, bridging, siding and

flooring. In the cutting of circular holes for column head forms a radius rod, adjustable to different size circles, guides the tool around a perfect circumference.

Five of these machines are now in use by the Ferro-Concrete Construction Co., Cincinnati, Ohio, whose president, W. P. Anderson, makes the following comments on the operation of the equipment:

"One of the great advantages of the machine is that it is portable and can easily be taken to any job where electric current is available or moved around to any point on the job. The illustration herewith shows the machine in use for cutting a round hole for a column cap; with it one man can cut five holes where only one could be cut by hand."

"The other principal use we make of the machine is in cutting panels and this can be done on the bench where panels are made. The machine cuts, measures and squares the ends of the form, and is so flexible and evenly balanced that only one motion of the arm is necessary to get either square or beveled ends. This enables us to increase our output 25 to 30 per cent with the same amount of labor as was formerly used when the panel had to be cut by hand. In fact, the form ends

can be cut off in less time than it formerly took to mark the lines for hand-sawing. The use of this machine with our company is confined principally to form-making but I believe it will effect a greater saving to house-builders than it does to us, as it could practically do all millwork in house construction."

Compact Air Motor Hoist for 500-Lb. Loads

For lifting and handling loads up to 500 lb. in repair or assembly shops the Ingersoll-Rand Co., New York, has placed upon the market a new air motor

hoist for loads too heavy for one man. This hoist operates on air pressures from 60 to 100 lb., has a lifting speed of 50 ft. per minute, a maximum lift of 15 ft., uses 3-in. wire rope and weighs 150 lb.

A feature of this equipment is an automatic brake which holds the load even if the air supply be disconnected or fail. A balanced three-cylinder motor operates in either direction, without vibration, and is geared through a mechanical train to the hoisting drum. A graduated throttle permits close regulation of both lifting and lowering speeds. Motor and gears are inclosed, the former operating in a bath of oil and the latter in heavy grease. In place of the top hook shown in the accompanying illustration a roller-bearing, monorail trolley can be supplied.

Publications from the Construction Industry

Truck-Mounted Crane—BYERS MACHINE Co., Ravenna, Ohio, illustrates a variety of uses of its Truckcrane in a 16-p. pamphlet. The crane, which can be mounted on the chassis of any 5-ton motor truck, has a 25-ft. latticed steel boom designed to handle a 3-yd. clam-shell bucket. Among the operations on which the use of the mobile crane is shown are the handling of batch boxes from truck to paver on road work, transferring sand or crushed stone from railway cars to trucks, stock piling sand, excavating in a gravel pit, unloading coal cars, earth excavation for building foundations.

Concrete Mixers—JAEGER MACHINE Co., Columbus, Ohio, has published a 48-p. illustrated booklet on its tilting-drum type of concrete mixer with capacities of 3, 4, 7, and 14 cu.ft. Most of the mixers illustrated are equipped with power loaders and a new tip-over water tank. A feature of the mixer equipment is the company's new vibrating distributor in the form of a chute which is subjected to a jarring movement in order to distribute semi-dry mixed concrete which would not otherwise flow down to the trough from the discharge end of the mixer. A portion of the text is devoted to the Jaeger concrete placing plant which includes an inclined track, skip, hopper and chutes.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Japan Will Require Three Billion Feet of Lumber

Output Is Equal To Demand Provided
Japanese Will Accept Ordinary
Building Sizes and Grades

The Douglas Fir Exploitation and Export Co. will send a commission to Japan early in November. The object of the mission according to the National Lumber Manufacturers' Association is "to provide technical assistance in rebuilding the devastated region and to encourage the Japanese to modify the sizes and specifications of lumber which they have required for their use, so that a large proportion of the products of the American logs can be utilized in meeting the needs of Japan.

"It is estimated that it will require over a thousand shiploads of three million feet each to rebuild the devastated areas, and America is the only country that can quickly respond and whose output is equal to such a demand."

The Japanese trade, according to the Association, formerly called for squares, ranging in size from 4 x 4 in. (10 to 20 ft. lengths) to 24 x 24 in. (24 to 40 ft. lengths) all in merchantable grade.

The combined resources of British Columbia, Washington and Oregon cannot furnish over a billion ft. of these sizes and grades in a year, says a prominent lumberman of the West Coast, and if the demand is as great as estimated, lower grades and sizes must be used.

"The large squares," states the report, "especially must be produced from the cream of the log, leaving a large proportion of side lumber not suitable for the demands of the Japanese. This is not in the interest of conservation, nor is it in accordance with the standardization program. If the Japanese will use ordinary building sizes of lumber they can secure more lumber at lower price, and this will tend to prevent a more or less acute situation in the domestic market."

Reports to the U. S. Department of Commerce place the destruction of buildings at 316,000 in Tokio and 70,000 in Yokohama. At the time of the disaster, large reserve stocks of lumber were stored in Kobe, Osaka, Tokio and other cities. With the destruction of stocks in Yokohama and Tokio, there would still be a fairly good supply left in the other cities for immediate emergency purposes. The real demand, according to the lumber manufacturers, will come when the permanent construction of the devastated areas commences.

Advices received from the Consulate General of Japan at New York, and made public by the U. S. Department of Commerce, state that by an Imperial ordinance, building materials and necessities of life will be exempted from import duty until March 31, 1924.

Next week—Essential data on
fifty large contracts awarded since
March—Total value \$157,460,646.

5,967 contracts reported by Engineering News-Record

for seven months, Mar. 1 to Oct. 1

\$1,324,642,000	

Foreign Projects of Interest to Americans

A number of foreign construction projects which should be of interest to American engineers, contractors and manufacturers has just been reported by the United States Department of Commerce. They are merely noted here, further information being available at the Bureau of Foreign and Domestic Commerce or its district of co-operative offices, when a reference number is given.

A Spanish city, through its governing council, has appropriated \$1,500,000 for the construction of low-price houses. The appropriation is for subsidizing concessionaires in order to relieve the housing shortage among the laboring classes. Subsidies of from \$30,000 to \$300,000, representing 30 per cent of the total estimated cost of the houses, have been granted to six companies.

Plans have been approved by the Minister of Public Works for a pontoon bridge to connect two Danish cities. The cost is estimated at \$2,412,000, at present exchange. Reference No. 35x-1.

A Lithuanian city has approved plans for a water and sewerage system to cost \$2,000,000, and it is proposed to grant a concession to some foreign construction company. Reference No. 105,546.

In a city in India extensive hydro-electric plans are underway. One of the projects is a dam 190 ft. high and more than a mile in length. It is stated that this dam will exceed the Assuan dam by 3,000,000 cu.ft. of masonry.

The Indian Stores Department is calling for bids on equipment for two large hydro-electric projects. Reference No. 106,908.

Bids Wanted on Chinese Bridge

The Hai Ho Conservancy Commission, Tientsin, North China, will receive tenders until May 1, 1924, for the construction of a bascule or other type of opening bridge over the Hai Ho River. The new bridge will be 306 ft. long, with a 40 ft. roadway with 9 ft. sidewalks on either side. The moveable span is to be of such design that when the bridge is opened the fairway will be 140 ft. The estimated cost is \$550,000. Specifications are filed with the Bureau of Foreign and Domestic Commerce.

Many More Projects This Year Than Last

Reports published in Construction News in the first half of 1923 number 2,263 more than in the first half of 1922 for the United States alone. This is an increase of 16 per cent. Detailed figures are given in two tables on p. 207 of last week's Construction News.

Every section of the country reflects this greater activity, with the exception of the South. Southern projects totaled 1,763 in the first six months of 1923, against 1,787 last year. On the other hand the 412 contracts awarded there this year averaged \$230,000, whereas last year's 411 awards averaged \$219,000.

In the entire United States the 4,362 awards reported by *Engineering News-Record* aggregated \$1,047,230,000, an average of \$240,000. In the same period last year the 3,895 contracts totaled \$779,767,000, an average of \$200,000.

Minimum costs of these projects are as follows: Water-works, \$15,000; other public works, \$25,000; industrial construction, \$40,000; commercial buildings, \$150,000.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 215 to 226, are the following:

Subway, Brooklyn, N. Y., to T. A. Gillespie, New York City, \$1,725,884.

(Continued on p. 662)

Building Equipment Required for News-Record Contracts

For the \$868,529,000 worth of industrial and building contracts noted in *Engineering News-Record* from Jan. 1 to Oct. 1, plumbing, heating and lighting equipment, paint and elevators to the value of \$118,000,000 has been or will be purchased. This year's large contracts for industrial expansion have exceeded \$200,000,000. Commercial building awards amounting to \$150,000 or larger, aggregate \$667,136,000. The money value of the painting and equipment required for both the industrial works and the large building contracts published in Construction News during the last nine months is estimated as follows:

	Industrial Works	Buildings
Plumbing	\$1,040,000	\$13,310,000
Heating	7,200,000	33,350,000
Lighting	5,549,000	23,545,000
Elevators	1,000,000	13,340,000
Painting	6,320,000	13,340,000
	\$21,100,000	\$96,715,000

Bids wanted on big water-works job at Denver, Colo., by Board of Water Commissioners. Work involves 96 tons of special castings. Total value, \$327,000. B. Lowther, engineer.

Car Loadings Break All Records

Freight loadings for the week ended Sept. 29, totaled 1,097,274 cars, the greatest number for any one week in the history of American railroads. This exceeds by 4,707 cars, the previous record which was established for the week of Sept. 1, when the total was 1,092,567 cars. Seasonal crop and coal movements are responsible for the increase.

Public Bond Sales Dull During Last Three Months

The month of September did not show any more activity in the sale of state and municipal bonds than the months of July and August. The *Commercial and Financial Chronicle* reports the total of long term bonds for September to be \$50,216,404 against \$51,345,526 for last month and \$99,776,656 for September a year ago. The largest issues of the last month were the \$5,000,000 North Carolina, 5½ per cent, 2-yr. notes; the several bonds of the City of Buffalo, N. Y., totaling \$3,510,000 at 4½ per cent; and the waterworks bonds of Cleveland, O., for \$3,360,000 at 4½ per cent.

During September \$11,102,000 United States municipal bonds were offered without success.

Of the 40 representative bond issues included in the accompanying table, six were sold at par, three below and the remainder above. The yields ranged from 4 to 5.99 and the rate of interest from 4 to 6 per cent.

Large Contracts Let During Week

(continued from p. 661)

Power Station, Kearny, N. J., to Public Service Production Corporation, Newark, about \$20,000,000.
Offices, Los Angeles, Calif., to P. J. Walker Co., San Francisco, \$1,850,000.
Hospital, Nashville, Tenn., to Hegeman-Harris Co., New York City, \$2,000,000.

Factory, Ottawa, Ill., to Jobst & Son, Peoria, over \$5,000,000.

Lock, Illinois, to Green & Sons Co., Chicago, \$1,460,012.

Hotel, Chicago, Ill., to Paschen Bros., \$2,250,000.

Lock, Pittsburgh, Pa., to Dravo Contracting Co., \$738,590.

Disposal Plants, Pittsford and

Brighton, N. Y., to P. H. Murray, Rochester, \$223,936.

Sewerage System, Brighton, N. Y., to Oakwood Constr. Co., Detroit, Mich., \$393,467.

Sanitary Sewers, Pittsford, N. Y., to Rauber and Vicinus, Rochester, \$131,690.

Conduit, Portland, Ore., to Willamette Iron & Steel Works, \$2,571,404.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted.

Valuable suggestions on costs of work can be had by noting actual biddings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Oct. 4; the next, on Nov. 1.

Steel Products:	New York	Atlanta	Dallas	Chicago	Minneapolis	Denver	San Francisco	Seattle	Montreal

Explanation of Prices—Prices are as to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or — signs. For steel pipe, the prevailing discount from list price is given: 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b. Labor—Concrete laborers' rate, 93c.; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. Tile price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu. yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5x8 x 14. Prices are all f.o.b. warehouses except C. I. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir, common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on pine lumber. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 98.64). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$47.42; 6-in., \$119.

Changes Since Last Week

throughout the entire country.

Common brick are quoted at \$19@20 per M., wholesale, alongside dock, New York, against \$20, one week ago. The fluctuation is due mainly to heavy brick reserves being stored in the Hudson River district and to importations of considerable quantities of foreign brick. Extensive demolition of old buildings in New York, is throwing large quantities of second-hand brick upon the market, which have been quoted as low as \$14 per thousand.

While San Francisco reports an advance of 3c. per gal. in linseed oil, the recent downward trend has not yet abated as evidenced by declines of 1c. and 2c. per gal., reported in Dallas and

Montreal, respectively.

The iron and steel situation may be briefly outlined as follows: Pig-iron sales dropped to half of usual volume. Consumers purchasing on basis of month to month requirements. Japan will need about 60,000 tons of galvanized steel sheets. Japanese buying on strictly competitive basis, hence, several large steel orders placed in Germany. Steel plates firm at \$2.50 per 100 lb., Pittsburgh, with reports of shading to \$2.40. Structural market quiet but with no evidence of weakness; quotations holding firmly at \$2.50. Bars firm at \$2.40 base. Rest of steel list firm with exception of shading in black sheets and decline in scrap.

Although a certain amount of stimulation is noticeable in the current market, most buyers are limiting purchases to actual requirements. The fact that domestic buying is confined to small lots and that the Japanese demand has not yet exerted its full effect upon materials resources, few changes, either up or down, are noticeable in the price tables.

Seattle reports a drop of 50c. per 100 lb. in structural rivets and Dallas, an advance of 5c. in reinforcing bars, due to scarcity of local stocks. Cast-iron pipe dropped \$1 per ton and 3-in. gravel, 5c. per cu. yd. in Atlanta.

Concreting materials and lumber remain firm, with few exceptions,

Volume 91

NEW YORK, OCTOBER 25, 1923

Number 17

When Water Is Missed

IT'S a severe drought that does not do some good. In northeastern New Jersey many communities that had long postponed joining Newark in the development of the Wanauque supply have taken decisive action since the accumulated deficiency in this year's rainfall has caused serious water shortage in adjacent territory. In northeastern Massachusetts, too, a number of communities have been short of water of late. Some of these have been helped out from the Boston Metropolitan supply—sharply emphasizing their possible dereliction in not having joined the district long ago as well as bringing home to the whole district the fact that it, too, may be short of water if it does not go further afield at once. New York City began none too soon on its Schoharie Creek enlargement, this year's low rainfall and the low stage of the Ashokan reservoir indicate. The Hackensack Water Co., which supplies over fifty New Jersey municipalities in Hudson and Bergen counties, has an immense reservoir about ready for service. It showed foresight in building this. Had it not been for presumably unavoidable delays in its completion this reservoir might have made it unnecessary for the company to cut off the supply to dozens of industrial plants last week, thus throwing thousands out of work. All these things bring home to the people and the municipal authorities, what every engineer well knows, that in times of plenty of water money and other means should be provided to guard against droughts, for water is sadly missed when the well runs dry.

Earthquakes and Modern Structures

ENGINEERS who have been awaiting details as to the effect on engineering structures of Japan's earthquake tragedy of Sept. 1 will find the first authoritative engineering information in the report, elsewhere in this issue, by John W. Doty and W. W. Johnston, president and engineer, respectively, of The Foundation Co., New York. While conditions after the catastrophe prevented an exhaustive technical study of all structures demolished or standing, it was possible for these two American engineers to make a rapid survey of what the quake did in both Japan's capital and one of its principal seaports 18 miles distant. The most significant message Mr. Doty brings back from the Orient is that modern building design can produce structures which will stand up even when subjected to a test as severe as that of the Japanese earthquake last month. In such design, however, swaybracing must be extremely heavy and the various elements of the structure, particularly the floors and side walls, must be securely tied together to resist the battering ram effects of a severe and sustained seismic shock. Structural adequacy, however, is only a part of the story. An examination of the devastated areas in the Japanese cities indicates that the fire which followed the quake was responsible for a considerable

portion of the destruction. The engineering lesson of the quake, therefore, must include a realization of the need, in any large city, subject to shocks, of fire prevention zones. In the rebuilding of the stricken cities it is certain that the authorities will prohibit, or at least minimize, the flimsy, top-heavy structure, and will lay out new work in accordance with a plan which will provide fire stops where needed. The government's first move toward these ends was the recent issuance of orders prohibiting the erection of any but temporary structures without a permit from the state.

Improved Road Contracts Again

CONTRACTUAL policies in highway construction were agreed upon a year ago by a joint committee of the Associated General Contractors and Association of State Highway Officials. They established a distinct advance in fair dealing. There remains the task of translating these approved policies into actual practices by state highway departments. This has already been done in some states. The results are satisfactory. One, therefore, is not proposing unprecedented action in asking that the joint committee, which has remained in existence and will next month go into conference to formulate its report, shall require that its conclusions shall be made articulate in state specifications and contracts for road construction. Until this is done generally the agreement reached last year is only a gesture. Such facilities have been too common in the work of contractors and engineers toward improvements in contract practice. In the road improvement of a decade to come the two have to work together in public service. If the agreement made a year ago is wise let it be enforced; if it is not wise let it be altered. Inaction is not worthy of either association.

Asphalt Simplified

ASPHALT simplification by the reduction to ten in the grades or varieties called for in specifications for street road work is now an accomplished fact. The Department of Commerce has just announced that, as a result of endorsement of the ten standard grades (as determined by penetration limits) by most of the state highway departments the leading engineering and specification-making organizations of the country and a substantial majority of the important producing companies, the new standards become effective Jan. 1, 1924, and form the Commerce Department's "Simplified Practice Recommendation No. 4—Asphalt." The new scale of grades (see *Engineering News-Record*, Oct. 18 p. 658) represents the joint recommendation of consumers and producers. It replaces the 50 or 100 different grades which it has been the practice to specify in the past. The obligation of highway engineers and contractors, however, does not end with the attachment of an O. K. to a report. The full fruits of the various asphalt conferences which have been held in Washington during the past year will be realized only if the asphalt users

specify, in their orders, one or more of the standard grades of material. The range of standard penetration limits adopted is sufficient to provide for every reasonable requirement of traffic or temperature.

Three in the Field

NOW that a sanitary section has been organized in the American Society of Civil Engineers there are three organizations depending almost wholly upon the same group of men for support. The two others are the State Sanitary Engineers and the Sanitary Engineering Section of the American Public Health Association. The meeting of the latter at Boston two weeks ago was so well attended—perhaps a hundred in all—and the four sessions, including the special conference on the treasury water standard, were so successful as to leave no question about there being a place for that organization. The State Sanitary Engineers have a distinctive field, being made up of the chief engineers of state health departments and a limited representation from the United States Public Health Service. As the newcomer in the field, the Sanitary Section of the Am. Soc. C. E. is on trial. However, the success of the informal dinners attended for the past few years by the sanitary engineers afford reason for believing that the more formal section will justify its existence, provided its meetings are judiciously handled in view of the existence of the other two organizations.

Water Pollution and Industrial Wastes

FOR many years past the problem of protecting the natural waters of the country from pollution by industrial wastes has been growing in seriousness. While there have been notable instances of progress, for the most part these have been isolated. From the viewpoint of governmental control, whether local, state, or federal, comparatively little has been accomplished beyond a long series of investigations and reports that have pointed the way to better things. Perhaps the greatest hindrance to progress has been the halting state legislation for the control of the pollution of waters by industrial wastes. There have been plenty of instances of sweeping prohibition of water pollution of any kind, but rarely has a statute been enacted that was, after all, much more than a formality since it is a well-known maxim that legislation without means of enforcement is futile.

Most of such legislation as has been enacted by our states has vested some degree of stream pollution control by industrial wastes in state boards or departments of health. Aside from the indefiniteness of some of this legislation and the lack of means of enforcement in nearly all cases, state health departments have been loath to undertake control of industrial wastes. This has been due to fear of political interference in case sufficiently strong action was taken to lead important industries of the state to expect great expense and trouble; and fear that the commotion thus stirred up might seriously interfere with work more vitally affecting the public health. To this, there may be added the inherent difficulties and complexities of the problem due both to the technical difficulties involved in treating many classes of industrial wastes and due also to an honest and legitimate concern for the industries themselves lest they be burdened with expense that might in extreme cases even drive them out of business.

Who should bear the burden of protecting our natural waters from pollution by industrial wastes? Some who fail or are unwilling to see that the growth of both city population and of industry makes impossible the keeping of many of our streams in what, to use the favorite phrase, is their "pristine purity," advocate unthinking and unreasonable extremes. If, instead of following them, a sane policy is pursued, there is no question but what the cost of adequate measures for protection in this field should enter into the legitimate cost of the products of industry and be met by the ultimate consumer. But so long as attempts to prevent water pollution by industrial wastes have been scattered here and there throughout the country with no well considered legislation and no ample means of enforcement as a rule, it has been only too apparent to any intelligent owner of an industrial plant that if he went to considerable expense to treat his wastes before they were discharged into whatever waters were nearest at hand, he would be handicapped by the fact that most, if not practically all, of his competitors were not even being seriously asked to assume a like burden of treatment.

Here, perhaps, is the greatest of the problems to be solved before material progress can be made in industrial wastes control. Fortunately, there is much encouragement of late in the growing willingness of manufacturers to co-operate with state authorities for the protection of our natural waters, provided only the authorities are reasonable in their requests.

The foregoing and many other considerations pertinent to this matter were either specifically or inferentially brought out at the stream pollution conference held at Philadelphia last week and reported in this issue. Much was also learned along these lines during the meeting of the American Public Health Association in Boston two weeks ago, when the sanitary engineering section of that organization devoted an afternoon to visiting industrial plants on the Neponset River, where two paper mills and a combined tannery and wool storing plant are each operating works for the treatment of their wastes that are on a par for complexity of the problems presented, the means used, and technical supervision exercised with almost any municipal sewage treatment plant in existence. This is in Massachusetts, and the results achieved there are attributed very largely to the reasonableness with which that state has proceeded in acting upon legislation passed years ago which on its face provided for very drastic action against these manufacturers.

One of the most hopeful indications of progress in sane measures of state control is reported by the action taken in Pennsylvania the present year. There the State Sanitary Water Board, created this year, is bringing together and co-ordinating the efforts of various state agencies having powers and duties in the field of the prevention of water pollution by industrial waste. Following and endorsing the later sane practice of the State Department of Health—as contrasted with the earlier idealistic attempts to stop all sorts of municipal sewage pollution at once—the streams of Pennsylvania have been divided into three classes and means for their protection against pollution both by municipal sewage and by industrial waste will be carried on accordingly. It is recognized that sewage disposal by dilution is legitimate; that some of the streams of the state are, for the present at least, so much given over

to sewage disposal that little can be done to reclaim them; that other streams are in a middle class and may be so treated; and that still others are but slightly polluted and should be carefully guarded—but all in accordance with the rule of reason, as to the expenditure of money, the burden that will thus be placed upon industrial and upon municipal treasuries, and the good of one sort or another that may be achieved by limiting or preventing pollution.

The protection of streams against pollution by industrial waste is a most promising field for work on the part of the engineer who can be both progressive and reasonably conservative, and who always bears in mind the value of the results that can be achieved from the measures which he proposes as compared with returns that could be gained for the same expenditures for another beneficial purpose.

What Is the Matter with Reclamation?

FOR twenty-one years the government has been at work reclaiming the arid public lands of the West. In that time hundreds of structures have been built and thousands of miles of canals have been dug so that eventually new homes might grow on land up till then made useless by lack of rain. It has been an enormous enterprise, costing millions today in order that future generations may benefit, and engaging the services of a fair proportion of our Western engineers. Yet during all this time the great body of the engineering profession—not being engaged in reclamation—has known of the work only casually. It has, to be sure, read with interest and pride of the large and excellent engineering structures which the government engineers have built. It has learned many things in hydraulic practice which it has applied to works other than those of irrigation. It has believed that the irrigation of government lands is an engineering problem, which is being solved with a fair degree of satisfaction by engineers.

The time has now come when engineers generally must take a more active interest in government reclamation. During all these two decades there has been another side to the problem—a political and a speculative side which culminated in the action of the present Secretary of the Interior in the removal of Arthur P. Davis as director of the United States Reclamation Service last July. The engineers engaged in irrigation have been long acquainted with this sinister aspect of reclamation. The engineers of the whole Western slope, in fact, know about it; but taken by and large the engineers of the country have not appreciated it. They have not known of the efforts underground and above ground which have been made to get Congress and the Department of the Interior to repudiate the law on which the reclamation of our public lands is based. They have not known the degree to which the land shark has robbed the settler of his heritage. They do not know the insistent political pressure that has been constantly brought to increase the profit of early holders at the expense of the rest of the country and of the future property owners on the reclaimed land.

All of this sinister influence came to a head last July, when Dr. Work sought to take control of the Service from the hands of the engineers and put it in the hands of the politicians. This act aroused the engineers of the country. It became evident that it was

necessary that engineers everywhere should know about the operations of a service with which their fellow engineers were so intimately connected and the fortunes of which are tied up not only with the fortunes of the engineering profession but with the integrity of the government service and the proper development of the country as a whole. To inform the engineers of the country of the true inwardness of federal reclamation is the main purpose of the series of articles which start in this issue. The series is not partisan; it is not political. It is an honest effort to present to the engineers of the United States and through them to the rest of the thinking people of the United States an impartial picture of the reclamation of our federal arid lands. The future of the country depends upon the judicious development of its resources, and no resource is more important than the farm homes of the next generation. If the development of those homes is to be restricted by malign political influence, the people should learn about it in time to stop such an influence. The very evident demoralization of the Reclamation Service which has already set in from Dr. Work's performance of last July and the stimulus given to those who have long attacked the sound management of reclamation make it all the more urgent that Congress should act, and act soon, to assure security of the present development and to lay down a sound future policy for the more difficult problems ahead.

It is now the time to review the practical workings of the early policies of administration and it is to the engineers of the country that the rest of the country must look for an interpretation of the history of that work. It is certain that the enterprise has been vital to the West; that it has been efficient in plan and construction and operation. It is equally certain that it has not been perfect. The attention of the whole country should now be called to the defects of the law for the earliest revision, for the elimination of political control, and the broadening of the law to suit the coming needs of the West and elsewhere. In this the engineer can be of service. If every engineer, whether he has direct interest in irrigation or not, if he has only an interest in the proper development of his country and a justification of his profession, will read the articles which are to comprise the series and will act on the facts set forth in those articles, the engineering profession can do a great work in forwarding the reform necessary for the proper control of reclamation.

It is not the purpose here to describe methods or forecast results. We only urge upon every engineer reader the universality of the problems of reclamation. Let him read the story of its development and its application. Let him trace the story of the Reclamation Service from its Rooseveltian beginning to its latest demoralization. Let him realize how the science of irrigation, though reaching back to the beginnings of history, is still a new science with new facts and new troubles developing every year. Let him understand the degree to which the world-wide economic upheaval since 1914 has overthrown early dreams and theories in the irrigation country. And finally let him see how the thread of engineering control must run through all this if the fabric is to wear. Government reclamation of land is a great and continuing engineering problem. If this new series in *Engineering News-Record* can convince engineers of that—and through them Congress—we shall be content.

Federal Land Reclamation: A National Problem

1. Origin, Problems and Achievements of Federal Land Reclamation.

By F. H. NEWELL

Formerly Director, U. S. Reclamation Service

The First of a Series of Articles on the History and Performance of the Great Government Adventure in Irrigation of the Arid Lands of the West.

TO ALL engineers and in fact to all taxpayers and citizens, there is a peculiar interest in the life story of the U. S. Reclamation Service. The present time is appropriate for a review of its operations because of the fact that its history is now practically a closed chapter; the Service, as such, ceased to exist 21 years—almost to a day—after its creation. The work may continue as a bureau organization, but the feature which characterized the inception and development of its work has ceased to exist, namely, that this was an organization planned and officered by engineers, exemplifying the highest ideals of the engineering profession.

A review of the origin and development of the Reclamation Service is of importance at the present time not merely as a matter of history, but because citizens and taxpayers in various portions of the country are urging their representatives in Congress to adopt a broad national policy of land reclamation and settlement. This will involve expenditures of millions of dollars, not merely of federal funds, but of corporate and private moneys, in the creation of opportunities for more rural homes. A wise expenditure of these vast sums, which must be made as demands arise for more land, is dependent largely upon a full and correct knowledge of what has already been accomplished and particularly of the errors which should be avoided and of the mistakes which are inseparable with undertakings of this character unless careful study is given to similar undertakings. Public opinion must be guided not merely by sentiment or good intention, but by the hard facts of experience such as the engineer with his exact training alone can develop. While the engineer must necessarily be a man of vision, yet at no time can he afford to be visionary. "Without vision the people perish," without the dreams of the engineers, modern civilization would be impossible.

How Federal Reclamation Began

Taking it as a whole, the Service is an illustration that dreams sometimes come true. It accomplished in its life of twenty-one years larger results than had been seen by the dreamers, the men of vision, who looked forward to great accomplishment. The works which have been completed exceed in magnitude those which were anticipated, and the results in agricultural productivity far surpass the estimates made by its best friends. But the object of the advocates of the original reclamation act was to "make men, not money," and to do this through creating opportunities for small self-supporting farm homes on the vast area of vacant public lands. From such homes have come the leading men of our nation. The results achieved are therefore to be measured in true home-making, not in money profits.

Much of the vacant public land in the West had already passed out of the control of Congress when the reclamation act was passed in 1902, but many millions of acres remained, as shown in Fig. 1, including areas

of fertile soil which might be cultivated, if only some natural obstacles could be removed, principally, the lack of water. Private capital had already been utilized in bringing water to ten million acres of these lands; all of the easily available localities where water might be had or applied to public lands had been taken up under one or another of the public land laws. But it was found that the large irrigation works needed for other

FIG. 1.—VACANT PUBLIC LAND IN THE WEST IN 1902
When reclamation started there was much vacant public land available. Contrast the blackness of this map with that of Fig. 2, opposite.

of these lands were beyond the reach of individual or corporate efforts, largely because the cost of reclamation was too great to yield a profit on the investment.

In 1888, the Congress of the United States had been persuaded by Major John Wesley Powell, the explorer of the Grand Canyon of the Colorado, at that time Director of the U. S. Geological Survey, to make an appropriation to ascertain the extent to which the arid region might be reclaimed and utilized in the making of homes for citizens. In his topographic mapping and geologic studies of the West, Major Powell had become impressed not only with the mineral wealth of the region, but, more than this, with the opportunities for homemaking in the fertile valleys. He had published in 1879 under the auspices of the Smithsonian Institution his classic statement on "The Lands of the Arid Region." Subsequently he had left no stone unturned to bring the mineral and especially the agricultural importance of the West to the knowledge of scientific men and of Congress.

The surveys and examinations begun in 1888 attracted wide attention and, when added to the results of the data accumulated by the census of 1890, showed a condition of affairs which demanded public consideration. These facts indicated that further development of the arid lands might be indefinitely delayed unless the Government, the owner of the vast extent of public lands, made some effort to reclaim these lands. The data showed that practically all of the plow lands, such as had been available on the great plains and had furnished homes for millions of citizens, had passed into private ownership, largely speculative. If population was to increase, or even to hold its own in the vast arid states of the West, it would be necessary to make some radical departure and to remove the obstacles which were preventing additional homemaking.

Although the public began to awaken to the necessity of taking some action looking toward the better use of the public lands, there set in a counter current

Office rules and regulations and thus the withdrawal of these publicly owned lands for purposes of reclamation interfered sadly with their plans of expansion.

In repealing, by act of Aug. 30, 1890, the permission to withdraw land for reclamation, Congress, however, provided that the "reservoir sites heretofore located or selected shall remain reserved." At the same time it, perhaps inadvertently, took a forward step, the importance of which was hardly recognized at the time. It provided "that in all patents for lands hereafter taken up," "there is reserved from the lands described a right of way thereon for ditches or canals constructed by the authority of the United States." At that time there was no authority for the government building such canals and the opponents of federal reclamation, that is, the large sheep and cattle men, were caught unawares. Thus, although the opportunities for future reclamation were greatly restricted, yet when the time came, ten years later, that the reclamation act was passed, it was possible to obtain necessary rights of way across public and privately owned lands under conditions far more reasonable than would have been possible had not this right of way been retained by the acts above noted.

In 1891 was held in Salt Lake City the first of a series of irrigation congresses. These were continued in successive years, with the result that public opinion gradually crystallized into a demand for action by Congress leading to federal recognition of the subject of land reclamation and settlement. The most active worker in Congress was Representative, later Senator, Francis G. Newlands of Nevada. He introduced bill after bill, but little consideration was given to the matter because of the usual objection by Congress to an increase of appropriations. Finally, the ingenious idea was wrought out, not of asking for a direct money appropriation, but achieving the desired results, without stating the quantity of money involved, by simply setting aside the proceeds from the disposal of public lands. These receipts had been shrinking rapidly, and, at the time the Newlands bill was under consideration, it looked as though the annual return to the Treasury would be less than a million dollars and would rapidly reach the vanishing point. Therefore, the prime objection to a reclamation policy was removed, as it was assumed that the amount actually available for such work would be quite small, and in any event would come from the states interested, and not through a direct tax levied upon the people of the whole country.

But even though the financial obstacle was removed, there did not appear to be enough general interest in the Newlands bill to secure action. The administration was indifferent and the leaders of both political parties were personally opposed to any such measure. It was not until the tragedy which brought Roosevelt to the presidency that the indifference was removed. One of the first acts of the new President, within a few days after being suddenly called to Washington, was to take up in private conference the whole subject of conservation, of forestry, and of reclamation. This he describes at length in chapter XI of his autobiography. As there described, he included in his first message to Congress his endorsement of the irrigation of the arid public lands. With this powerful advocacy, there was little delay, and on June 17, 1902 (Bunker Hill day), Roosevelt signed the reclamation act, making available the proceeds from disposal of public lands for the survey,

FIG. 2—VACANT PUBLIC LAND IN THE WEST IN 1922

Twenty years later the public lands of the West were practically all used up or reserved for park or forest.

against governmental action largely due to the fear, on the part of large land owners in the West, that the federal government would interfere with their systematic efforts in adding to their great acquisitions. Congress became stampeded for the moment and withdrew for a season further appropriations for investigation, stopping by act of Aug. 30, 1890, the setting aside of public lands which might be reclaimed and later, by act of March 3, 1891, restricting the reservoir sites and other lands needed for carrying out any plan of federal reclamation, specifying that such sites "shall contain only so much land as is actually necessary for the construction and maintenance of reservoirs, excluding as far as practicable lands occupied by actual settlers at the date of the location of the reservoirs." Demand for this arose from the fact that it was found that most of the best natural sites in the West had already been occupied in part as cattle or sheep ranches. The owners of these ranches in many instances had not taken the precaution of fully complying with the Land

examination, construction, and operation and maintenance, of irrigation works in the sixteen arid states.

The then Secretary of the Interior, Ethan Allen Hitchcock, of St. Louis, Mo., upon passage of the Reclamation Act in 1902, having had no experience and with little interest in the matter, promptly referred the whole subject to Charles D. Walcott, the Director of the U. S. Geological Survey. He was the successor of Major Powell, who had been entrusted by Congress with the topographic and hydrographic surveys of the arid regions. Walcott in turn designated as chief engineer, F. H. Newell, who since 1888 had been studying the extent to which the arid region might be reclaimed and who had become the chief hydrographer of the Survey. The Reclamation Service was accordingly organized without specific authority of law, but as an instrument in carrying out the object of the reclamation act. It was not a part of the Geological Survey, but operated in co-operation with it, as the instrumentality through which the Secretary of the Interior carried out the intent of the law.

Basic Policies of Federal Reclamation

At the time the Reclamation Act was signed—twenty-one years ago—conditions were far different than they are today; the ideas then prevalent are now seen to have been not only vague but not based upon full knowledge by Congress of the available facts. The law was purposely made quite general in character; it gave broad authority to the Secretary of the Interior to execute the work, but did not indicate how it should be done nor did it provide any specific agency. The assumption was made that the secretary would have the necessary work planned by some of his employees, and then let a contract for a specified piece of work; later he would collect from the landowners, benefited by these works, the estimated cost of construction in ten annual instalments without interest. There is probably no law as far-reaching in its consequences as this in which such large discretion has been imposed upon one official. This discretionary power was its strength and also its weakness. It allowed the work to be adapted to the conditions found to exist and yet at the same time it left to the personal judgment of each of a frequently changing series of incumbents the larger policies on which success was based.

The policies fixed in the act pertained largely to methods of initiation of the work and to withdrawal of lands, a matter which had been the subject of much controversy, as before indicated, because of the reluctance of western men to permit the United States to exercise a control over public lands used by them for cattle and sheep grazing. This they regarded as an interference with their inherent rights to occupy lands belonging to the public. Emphasis was placed also by law on the limitation of the acreage of reclaimed lands which might be taken or entered by any one citizen. It was provided that the limit of area per entry "shall represent the acreage which, in the opinion of the Secretary, may be reasonably required for the support of a family upon the lands in question." The law also provides that the charges which shall be made per acre upon the entries or reclaimed land "shall be determined with a view of returning to the Reclamation Fund the estimated cost of construction of the project, and shall be apportioned equitably." As a matter of fact the word "equitably" has been applied practically as being

synonymous with "equally," as it has been found impracticable to attempt to discriminate between adjacent farms or areas reclaimed by the same system, or to set terms which take into consideration differences of soil or location with respect to roads and centers of population.

The law also attempted to prevent non-resident ownership and provides that no right to the use of water "shall be sold to any land owner unless he be an actual bona fide resident on said land, or occupant thereof residing in the neighborhood of said land." Here, as in the case of the limit of entry, practice has developed most ingenious evasions of the object of the act, residence in the neighborhood being construed to include locations within 50 miles of the land, a single family or group of relatives occasionally holding several farm units, these being held in the name of the man, of his wife, of each son, and each daughter, of a brother, and so on.

The original law also required repayment in ten annual instalments, without interest, of the cost of water and provided for actual cultivation as well as residence.

It was necessary from time to time for the Secretary of the Interior to put into effect various principles which were not explicitly stated in the act but which could be inferred from its general object. It was fortunate that at the time of initiation of the reclamation work the men in direct charge had a large vision of the possibilities and a keen interest in the success of the law. President Roosevelt gave personal consideration to some of the larger principles and their application, being directly advised in this by Charles D. Walcott, the Director of the U. S. Geological Survey, with which the Reclamation Service was affiliated. In particular, the Secretary of the Interior from 1907 to 1909, James R. Garfield, brought to the law highly constructive efforts and ideals. In fact, it may be said that the larger policies of the Reclamation Service were developed under the immediate and personal consideration of Garfield.

At that time there was little or no urge that the smaller canals or distributing systems should be built by the government; practically all plans were made with the idea of carrying into effect the original conception, namely, that the government should build the reservoirs and main line canals and that the settlers, following the example of the older pioneers, should organize and build the small works themselves. Garfield devised and carried out an ingenious system by which this was being done. Unfortunately, his successor did not view the work in the same light and abolished the Garfield method, throwing upon the government enormous expenditures with the accompanying difficulties of building all of the minor works, even down to the fields of the farmers. To the abandonment of this principle of requiring the local land owners to help themselves as far as possible may be attributed many of the subsequent difficulties.

At that time there was no thought that the government would be called upon to go into all of these minor matters or be urged to actually level the small individual holdings and put these in condition for crop production. Congress and the people in general did not see the necessity for going beyond the original conception of the government building the larger works such as were beyond the ability of the pioneers. Thus no provision was made then for meeting the subsequent insist-

ent and rapidly growing demand for more and more work to be done at federal cost.

Complicating Conditions

Throughout the entire West there is more good land than there is water available for its reclamation. The choice, therefore, of areas to be reclaimed was limited not so much by the character of the land as by the location of the water. This fact had been brought out by the earlier surveys, but the people of the West in general had little conception of the limitations which existed as regards water supply.

Appropriation—To understand the conditions which confronted the Reclamation Service on the initiation of its work, it must be had clearly in mind that in the arid region the laws regarding the water are in one sense the reverse of the common law of England and that of the Eastern or humid states, where the so-called riparian laws prevail. These latter require that under ordinary conditions the waters of the streams shall be allowed to flow in their natural courses unchanged as to quantity or quality. In the arid region, the common need of the people, which ultimately assumes the force of common law, is that, if necessary, all of the water of a stream shall be taken out upon the dry lands. The water which ultimately returns to the stream through seepage, becomes greatly changed in quality since it receives the earthy salts or alkali washed out of the soil.

While in most of the Western states, legislation or court decisions established the doctrine of appropriation, in some states, as in California, the water laws were in a nebulous condition. In these states, the laws and decisions in some cases appeared to uphold riparian rights, in others, to limit or deny them, causing much uncertainty and delay in development.

Legal Limitations—The obstacles interposed by nature were less difficult and annoying than those just noted, of purely human origin, arising from neglect or abuse of the water laws. The Western representatives, aware of this condition and at the same time jealous of local rights and fearful that in some way these might jeopardize by federal interference, insisted upon the insertion in the reclamation act of a provision to the effect that all work executed under the terms of the reclamation act should be in conformity with state laws relating to water control. A few of the states, notably Wyoming, provided machinery and methods for ascertaining the amount of water in the various streams and the claims which were made to this water. In other states, however, the custom had grown up of each man's claiming everything in sight so that the aggregate of the claims often far exceeded the amount of water in the stream, and yet only a small part was actually being used.

It should be kept in mind that practically all of the best lands which might be available for reclamation had by 1902 already passed into the hands of individuals and from these had gone under corporate control. During the long years in which discussion dragged as to the possibility of Congress adopting a policy of reclamation, the enterprising citizens and the speculators, as well as the land and cattle companies, through their employees or friends, were extremely active in filing upon every acre of public land which might be developed and upon the waters in every stream throughout the arid region. This activity in acquiring reclaimable land was facilitated by the congressional acts of

1890 and 1891 above referred to, which prohibited public officials from withdrawing public lands excepting those actually needed for reservoirs.

Thus, when the time arrived that funds for reclamation were actually available, there were found to be many recently created obstacles. Some of the projects which would otherwise have been relatively simple and inexpensive of achievement, had necessarily to be passed over on account of these recently acquired rights in lands and waters; other more difficult projects had to be taken up—all of these having notable obstacles from the engineering standpoint. It is fortunate that at that time, during the initiation of the large works which have been carried on during the past twenty years, there was left in the hands of the Secretary of the Interior a large discretion which enabled the overcoming of some of these difficulties. Had it been necessary then, as it is now, to go to Congress for the solution of many of these details, it is easy to imagine that much of the work would not yet be started.

In shaping the original act, it was assumed that most of the land to be reclaimed was in public ownership and that this land would be entered upon after reclamation under the terms of the homestead act. In fact, the extension of the benefits of federal reclamation to the land in private ownership was of the nature of an afterthought on the part of the committee which had the matter in charge. Congress was with difficulty persuaded that the condition above described actually existed. As was ultimately shown, the privately owned land, reclaimed by public funds, has far exceeded in area and value the lands which were public at the time of the passage of the reclamation act and which have been opened to homestead entry under the terms of the act. The point has been frequently made that there can be little real difference as regards treatment between the land which was entered yesterday before reclamation and that which may be entered tomorrow after plans for reclamation have been adopted.

The first, the crucial, test of this principle came about immediately after the passage of the reclamation act in the case of the arid lands in the Salt River Valley in Arizona, near Phoenix, the capital city. Here were at least 200,000 acres of land which had already passed out of public ownership and on which some improvements had been made and lands cultivated in part with the inadequate water supply. Around these were a million acres of equally good land in public ownership open to homestead entry. The question was raised as to whether the water to be stored by expenditure of federal funds should be sold to the lands already in private ownership and then partly developed or be held for other adjacent lands to be taken up under the homestead act. If the latter course had been pursued, thousands of small land owners would have lost the value of the improvements already made; they would have been compelled to move and to re-establish their farms on other lands no better but for which the new water supply was provided. The decision was wisely reached that as between these alternatives the preference should be given to the land in the hands of small owners who had already spent all of their available means in attempting to make a home.

The situation was further complicated by the fact that in many localities there has been a conflict between the demands for water for irrigation and for development of hydro-electric power. Theoretically, the rights

to the use of the water should be based on a priority not strictly of time but to a large extent of use. In theory, preference should be given, first, to the needs for domestic and municipal supply, next to the production of food through irrigation, then to power and, last, to navigation. Where, however, power plants had already been established on the streams, particularly below points where water might be diverted for irrigation, it has been practically impossible to develop the irrigation projects without interfering with the vested rights of the owners of the power plants. Such conditions were found to exist, preventing the taking up of several enterprises. Where, however, the power developments were above the points of diversion for irrigation, then the difficulties were not so great. These

tion works. There is really no good reason why the money derived from disposal of public lands in any one state or group of states should be dedicated to home-making in any other restricted area. That is to say, there is no inherent right for Idaho, for example, to claim that the receipts from public lands in North or South Dakota, Oklahoma, or other states are, by any moral or ethical consideration, dedicated to use in Idaho rather than for use in Mississippi or Louisiana, from which states the proceeds of public lands have gone directly into the federal treasury. Nevertheless, there has been a strong sentiment that the West is a separate entity and that the public funds derived, for example, from Oklahoma, should be used in the reclamation of some area to the West rather than to the improvement of a body of land to the East in Arkansas or Louisiana.

The passage of the reclamation act, and the works proposed under it, had a stimulating effect on state legislatures in inducing them to provide adequate methods of adjudicating the quantity of water available. It was plainly evident that federal funds could not be used in reclamation until there was some assurance that the water stored or developed by the use of these funds could be made available permanently for the lands to which the irrigating canals were built.

In some cases, enterprises otherwise desirable were passed over because there was reasonable doubt as to whether other claimants might not be able to establish a prior right to the waters needed for the government works. Thus considerable time was lost and a large amount of energy expended in development of these matters which should have been given earlier attention by the state legislatures.

In the years immediately following the passage of the reclamation act, there was somewhat general indifference as regards the place of expenditure. The popular imagination had hardly awakened to the possibilities of reclamation in building up industries and land values. In fact, in several of the states such as California it was quite difficult to get the state officials and public bodies to co-operate in securing necessary rights and privileges such as would facilitate the expenditure of federal funds. This fact seems now almost inconceivable and yet throughout that great state, although many projects were examined, it was found necessary largely because of this indifference, to select a project on the extreme north of the border of Oregon and another in the extreme south on the border of Mexico. Every other intermediate project was in the hands of investors or was tied up in such way that federal reclamation was not then practicable.

This condition of relative indifference was afterwards appreciated to be highly beneficial as a whole because it delayed the growth of political pressure and the throwing of the reclamation fund back under the direct control of Congress, putting it, like the river and harbor appropriation, into what has been termed "the pork barrel." While this is hardly an appropriate characterization, yet even the greatest optimist is forced to admit that the local politicians, who were indifferent during the early years of the Reclamation Service, later became extremely active in urging their pet projects, even threatening the official life of the men who opposed them. On the whole, however, it may be said that there has been a minimum of politics mixed with the work of the Service. No human institution can be said to

FIG. 3.—RECLAMATION FUND, RECEIPTS AND EXPENDITURES BY STATES FOR 20 YEARS

obstacles, growing out of the acquisition of rights for power, are steadily adding to the complication of development of reclamation works.

Apportionment by States—The reclamation law, as originally passed, provided that where practicable the major portion of the funds arising from the sales of public lands in each state should be expended in that state. This clause was inserted as a concession to certain sectional influences. After a few years of practical operation, it was found that this provision of law had the effect of compelling the consideration of less meritorious projects in the states from which large funds were derived and that better projects in other states were being given less consideration. In fact, the need of reclamation was found to be in inverse proportion to the amount of money coming from a state. For example, the state having the largest area of public land, Nevada, has a climate so arid, with such small water supply, that the public lands cannot be sold, and yet at the same time the needs of reclamation are perhaps greater there than in other states where the lands were being rapidly disposed of. Although this provision was repealed on June 25, 1910, yet even now there continues to be a demand for construction in proportion to receipts from each state.

The present condition as regards receipts and approximate expenditures by states is given in Fig. 3, which indicates that the largest amount of money has come from Montana, while the largest amount of expenditure has been in Idaho, where about four times the amount of money received has been utilized in reclama-

be entirely free, but the older projects of the Reclamation Service are notable in this regard perhaps largely because of the condition before noted, namely, that the politicians had not discovered the opportunities!

Thus, although the original projects were permitted to develop almost entirely upon their physical and economic merits, yet at all times it was necessary to make adjustments and to undertake enterprises which did not turn out well. For example, the law required originally that some work be undertaken in Kansas; the best opportunity from the physical and economic standpoint was chosen and yet this did not succeed largely because the climate was not sufficiently arid. Experience has shown that the land owners will not practice irrigation habitually unless forced to do so by constantly recurring seasons of drought. An occasional wet year practically destroys the value of permanent irrigation work. These enterprises which had to be taken up because of legal requirements and which did not succeed economically in the aggregate, however, form a very small proportion of the total expenditures, so that the claim may be properly made that the percentage of failures due to all causes has been as small and possibly less than that of any large corporate undertaking. Judging from the biographies of great captains of industry—Hill, Harriman, Morgan, and others, the percentage of success attained by them in their investments is, to say the least, no greater than that of the investment of the reclamation fund.

Planning and Construction

Beginning with a few projects, which had already been examined by the Hydrographic Branch of the Geological Survey, step by step the work was entered upon in each of the reclamation states. Contracts were let and an organization was built up for doing those things which could not well be covered by the usual form of contract. It was found, for example, that the awarding of contracts for deep foundations for dams in relatively inaccessible places or for digging of tunnels under conditions which could not well be determined in advance, resulted in many failures and in protracted lawsuits. Better results could be obtained if the risks of such enterprises were assumed by the government directly rather than left to competitive bidding, especially where contracts under the law must be awarded to the lowest bidders, many of whom were then unskilled in this particular type of work. The best results were obtained where the government forces and the contractors were practically on a parity, in that the results of one method could be checked up against that of the other. The highest degree of economy and efficiency was secured through the competitive spirit thus developed.

Because of this relative freedom of organization and of method it was possible to build up in the Reclamation Service a morale or an *esprit de corps* such as has been rarely attained in government service. Every engineer, technician, or clerical employee, who has been connected with the Service, looks back with pride on those days when the organization was pushing ahead, carrying on its great work not only with a high degree of precision, but, more than this, with the feeling of mutual respect and confidence due to the free expression of minds unhampered by outside control.

The organization of the Reclamation Service kept pace with the selection of new projects and the letting

of contracts or beginning of work on these. In this selection consideration had first to be given, as before noted, to state lines because one of the requirements of law was that at least one project should be located in each state; hence the entering upon the Garden City project in Kansas, the Williston Pumping project in North Dakota, and a few others. Next to this was consideration of the existence of public lands. And here, as before stated, was encountered one of the first obstacles. For example, in Nevada the irrigable public land alternated with sections of land granted to the Central Pacific Railroad. Public exasperation against the railroad was such that the government was not justified in attempting to reclaim these public lands within the limits of the railroad land grant; moreover the railroad officials at that time were not inclined to make these lands available for reclamation and settlement, excepting under terms which were practically prohibitory. In this case, therefore, it was necessary to go outside of the railroad land grant limits and take lands which in some ways were less favorably situated.

Careful consideration was given to soil conditions, the probable extension of railroads, and possibly crops and markets. At that time the study of the soils was relatively in its infancy and while the soils were classified, yet few men dared to venture an opinion as to what kind of crops might be successfully grown after the lands had been irrigated a few years. They were wise in this position, because the outcome of twenty years' experience has shown that much of the soil then considered of the very best quality has become hard or impermeable to water, and other soils regarded as doubtful, have been transformed and are now productive. These changes are discussed by Carl S. Scofield in a succeeding article, but emphasis should be placed upon the fact that even today, with all the experience had, a man will be rash indeed who will attempt to select irrigable land on the basis of the ordinary soil survey and to predict what changes will occur during the next ten years.

This selection of land was of course controlled by the policy to obtain water and bring it by gravity to the highest point of each possible farm. Here the topography controlled, and while selection was made where practicable according to considerations of soil as well as climate, transportation and markets, yet the choice was necessarily narrowed down to the relatively few places where water could be had.

Moreover, the questions were not those simply of getting water but more than this of providing a quantity adequate for dry seasons and yet at the same time not restricting the area of land so greatly that the cost per acre would be excessive. In nearly all of the projects entered upon by the Reclamation Service some storage had to be provided. This is because of the fact that when the law was passed, all of the easily available sources of water had been filed upon and put to partial use leaving to the government only the excess water which came in irregular floods.

The problem of flood storage has been not merely that of holding enough water for the next year but of anticipating the probable demands for several successive years of drought. While it might be practicable to irrigate alfalfa for example, during a year of ample water supply, and then let the fields go without water during the next dry year, such course of procedure would be ruinous to orchards and to well planned sys-

tems of rotation. The providing of storage, therefore, is by no means a simple mechanical process but one involving careful judgment based upon long continued studies of the erratic water supply.

The one feature which characterizes work under the reclamation act, differentiating it from most of the private enterprises which had preceded it, was the relative permanence of all structures, especially of

FIG. 4.—LOCATION OF GOVERNMENT IRRIGATION PROJECTS

storage reservoirs, diversion dams, flumes, and similar works. In the case of private enterprise, the heavy interest charge on permanent investment on the money borrowed for construction necessitated keeping down this amount to the very minimum, thus utilizing wood for dams and flumes, even though it was known that these would decay within a few years. It was hoped that those wooden or temporary structures would hold together long enough to permit the investors to get their money back. In the case of government funds, however, bearing no interest charge, and devoted to works intended to last for centuries, the chief consideration was permanence, this being in the long run the highest economy.

The construction at the outset was as a rule by contract, but conditions forced the taking over of some of these contracts and completing them by daily labor. The experience thus acquired showed that the government engineers with ample funds available could really do the work at less cost, all things considered, than could the usual contractor who was compelled to buy equipment for each new piece of work and to borrow money often at ruinous rates. Thus grew up the so-called force account and construction accompanied by careful cost-keeping not only of the work done by the government but of that done by contractors so that at all times a comparison could be made of the relative economies of each system of work.

The engineers and all others connected with the work

were carefully selected by intelligent application of civil service rules. During the first decade at least, or until the politicians discovered the service, it can be truthfully claimed that not a single appointment or promotion was made for other than ability and merit. Thus was developed a somewhat remarkable body of men and today one of the greatest satisfactions is to find that practically every man and woman who has been connected with the Reclamation Service speaks of this connection with pride.

Out of this condition has grown perhaps a most remarkable series of engineering successes. It is true that, looking back, it would now be possible to improve some of the plans, but this can be done only because of the results developed in these earlier works. Many attacks have been made upon the Reclamation Service and for years congressional investigation committees took up one phase or another. At one time a body of army engineers was appointed by President Taft to make a study. Their report was highly gratifying and it is probable that no man in the Service would or could have written a more commendatory statement than that given in the cold language of an official report.

Work Done

Briefly enumerated, the total amount of work achieved may be summed up in the following statement: that on 26 projects located as shown in Fig. 4, water can be served to 3,000,000 acres in round numbers, including from these projects, 1,700,000 acres for which the government systems furnish the sole supply for irrigation. Of this latter, 1,200,000 are actually harvested. The total number of irrigated farms is 33,000 and the population of these farms, 125,000. The gross annual crop is valued at \$50,000,000. The increase in value of lands and other properties on farms and in towns, within the projects is estimated at \$550,000,000. The works as now constructed included 100 storage and diversion dams, reservoirs with a capacity of 10,000,000 acre-feet or storage, 4,000 miles of main line canals, and 8,000 miles of laterals or distributaries, 28 miles of tunnels, 140 miles of flumes, 9,100 bridges, and thousands of smaller structures.

Looking back over a stretch of twenty years of intimate connection with the engineering, technical, and administrative details of the Reclamation Service, there stand out amid the host of recollections certain impressive pictures. During this time over \$140,000,000 of federal funds have been invested in building large works of reclamation, some of them monumental in character, all designed, however, with the ultimate object of providing opportunities for small self-supporting farm homes. The results attained in number of homes and in crop produced have exceeded the expectations of the advocates of the reclamation law. At the same time, however, there have been disappointments and failures, such as are inseparably connected with any human enterprise.

From the purely engineering standpoint, there have been notable advances in methods and efficiency of construction. These have kept pace with the development of similar work elsewhere, since the operations under governmental control have been checked up continually against those handled by corporations or individuals. There has been a continual interchange of ideas, the government works have been visited at short intervals by engineers and experts from all parts of

the world, incidentally contributing information or advice, as well as receiving inspiration for inaugurating similar works in other countris, and in other parts of the United States.

The files of *Engineering News-Record* contain full descriptions of most of the notable works and of methods employed in construction, so that at this time it is hardly necessary to comment upon these other than to refer to the fact that these works have served to a certain extent as a training school for many of the engineers of the present generation and to a certain degree as a laboratory of research into details whose practical applications were needed in the completion of other undertakings.

With the completion of the works, however, it may be said that "the real trouble begins." Under the original conception of the act, it was assumed that as soon as the works were done the government in some way would step out and would be concerned merely with the collection of the cost. This, however, has not been the case. Instead of being able to step out, the government has become more and more entangled in petty personal details of peddling water to thousands of land owners. Among these land owners are good farmers on good lands having good results, and on the other extreme are inexperienced or poor farmers on poor land pursued by bad luck. In between are all gradations of ability, experience, strength, good health and good sense.

In general it may be said that the reclamation act in many ways is ideal, but to be successfully operated it must have ideal men and ideal communities such as do not yet exist. Most of the efforts of Congress since the passage of the reclamation act have been along the line of trying to patch it up to fit the needs of the inexperienced land owner, the "town farmer" or speculator. The ideal land owner and water user is not in the majority. Year by year efforts are being made here and there to lower the requirements of payment and to add more and more money to the fund to make up for the fact that payments are not promptly made. There is now quite a volume of law and decision so that it is rather difficult to gain a comprehension of the actual intent and operation of the law. Because of this, many citizens are urging that there be a rather complete revision of the law based on the experience of the past twenty years, strengthening the desirable portions and modifying other parts to meet conditions which have arisen. Moreover, the excellent results which have

come from the passage of the reclamation act have attracted the attention of taxpayers in other parts of the country and they in turn are asking that the law be made broad enough to cover the reclamation and use of waste lands in every and all parts of the United States.

[This is the first of a series of articles discussing the problems and progress of the Reclamation Service. The next article will appear next week.—EDITOR.]

Rebuilding Tournelle Bridge as Flood Protection Measure in Seine River

FOLLOWING the extraordinary flood in the Seine which caused much damage to property in the region of Paris in 1910, important engineering works have been conceived to limit damage which might be caused by similar conditions. These projects have been of diverse nature, designed to be carried on as a comprehensive whole. For instance the program includes construction designed both to facilitate the passage of flood waters through the Paris district as well as to reduce the intensity of flood waters.

In the first group of improvements is found the repair of the shore works of the Island of Saint Louis and of the Tournelle bridge. The reconstruction of the Tournelle bridge is now being carried on. The bridge has been demolished and a new structure is to be erected as soon as certain legal obstacles to reconstruction have been disposed of.

The Tournelle bridge was one of the oldest in Paris, having been built in 1654. Like all structures of its era, it contained semi-circular arches of small opening, making navigation more or less difficult, particularly during high water. In addition, during floods, free passage of water was impossible because of the number of piers, and the spandrel walls formed a dam when the water rose above the crown of the arches. This was the case in 1910, the key of four of the six arches having been submerged. The new design, says a recent issue of *Le Genie Civil*, contains a main reinforced-concrete arch 73.8 meters in span, resting on abutments 25 meters in length containing arches with opening of 11 meters and 11.50 meters, respectively.

The crown of the reconstructed arch is above the record water height of 1910. Passage of excessive flood waters is facilitated in another way by the new design which provides for the floor system to be carried on continuous columns spaced at 21-meter intervals.

ELEVATION OF OLD TOURNELLE BRIDGE AND DESIGN FOR NEW BRIDGE

Damaged Earth Dam Repaired by Hydraulic Fill

Over 300,000 Cu.Yd. Pumped Into Embankment.
Reduced by Settlement and Wave Action
—Pump Fed by Drag Bucket

BY M. E. BUNGER

Engineer, Model Land & Irrigation Co., Trinidad, Colo.

A LESSON of faulty embankment construction is contained in the series of repairs to the earth dam of the Model Land & Irrigation Co., near Trinidad, Colo. Incidentally the work illustrates an interesting combination of equipment for making hydraulic fill.

The dam for the Model Reservoir is an earth structure 5,900 ft. long and 45 ft. high. It was built with a 1 on 1½ slope on the inside and a 1 on 2 slope on the outside and an 18-ft. roadway on top. Teams and dump wagons were used and the fill was not puddled and received only such rolling as would occur from hauling over it. An unexpected flood showed the fallacy of such construction; the water went right through the structure. For some unknown reason, however, the earth above the hole caved in and stopped the flow and only a small amount of damage was done. The dam was then puddled by pumping water into it through holes jetted down from the top.

The inlet ditch of 3,000 sec.-ft. capacity comes into the reservoir at the south extremity of the dam, and

FIG. 2—PLANT LAYOUT FOR HYDRAULIC FILL OPERATIONS

tical elevation for a distance of 1,500 ft. in the center of the dam was completely destroyed. A partial failure also occurred on 2,500 ft. more of this facing on both sides of the center portion that failed. Where the concrete was not entirely destroyed the facing was repaired by placing over it a new layer, 4 in. thick, of 1:2:4 mix, reinforced with ½-in. square, twisted rods spaced 14 in. both ways. In the places where the old facing was destroyed the cavities were filled with earth and well puddled and a new layer of concrete 6 in. thick was placed over them. This repair work took care of 1,600 ft. of the facing.

On the next 1,500-ft. section where the concrete was entirely destroyed and over 2,000 cu.yd. of dam washed away, it was thought best to cut the face back to a 1 on 2 slope and face with riprap. It was thought that the riprap being rough would greatly decrease the wave action and would be more elastic than the concrete. The upper 19 ft. vertically of the dam for a distance of 1,500 ft. was then cut to a 1 on 2 slope and the earth used to build back the face. This earth was thoroughly puddled and packed. After this was done there was needed about 1,000 cu.yd. more to complete the face.

Hydraulic Fill Operation—The puddling of the dam and the manner in which it was built caused a settlement beginning with 0 at the north end and amounting to between 5 and 6 ft. in the center. It was necessary, in order to fill the reservoir to the capacity for which it was built, to build back this five or six feet. To increase the height and to maintain a roadway on top especially where the face was cut to a 1 on 2 slope, it was necessary to build up a layer of earth on the outside 27 ft. wide (Fig. 1). This work involved placing some 160,000 cu.yd. of earth, all of which if taken from without the reservoir would have to be hauled from the extreme ends of the dam as all suitable earth below had been used in building the dam originally.

Beginning at the south extremity of the dam and extending north for a distance of 2,800 ft., a large quantity of silt had been deposited, reaching a maximum depth of 20 ft. This silt extended out 1,000 ft. from the dam and was composed of layers of sand, gravel, silt and pure blue clay. The layers of clay varied from 2 in. to 4 ft. in thickness and were soft and boggy. It was figured that if a method could be found to utilize this material in the reservoir it would be cheaper on the south 2,900 ft. of the dam to place an embankment on the inside against the old facing and on top of the silt already deposited with a 1 on 10 slope on the in-

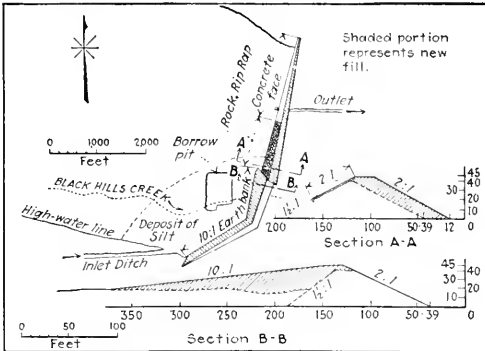

FIG. 1—PLAN AND SECTIONS SHOWING REPAIRS

as the outlet is near the north extremity the silt carried by the water was deposited along a greater portion of the inside face. This has been a great factor in sealing up the dam and making it safe for the storage of water.

On the inside the dam was faced with a 6-in. layer of concrete reinforced with hog wire fencing. The hog wire was placed longitudinally and the contractor was not careful to lap or fasten the wires. When the dam settled, lines of weakness developed at these points and the concrete face cracked. The waves, where these cracks occurred, would run up the concrete, enter the cracks and carry away the earth underneath. Concrete patches were put over the cracks but as no reinforcing was put in them, they would in turn crack and the earth was removed as before.

Several terrific wind-storms occurred during the month of May, 1920, while the reservoir was two-thirds full of water, with the result that the upper 19-ft. ver-

side, to resist wave action, than it would be to build up on the outside 27 ft. wide and repair the facing above the silt on the inside. It was decided to build a dredge in the lake and pump the material for the 1 on 10 slope on the inside for the south 2,900 ft. of the dam, and for the layer 27 ft. wide on the outside for the remaining portion and also to pump the material required to build back the face. The total volume to be moved was approximately 300,000 cu.yd. Pumping had the advantage of having the material thoroughly packed when it had settled and, where pumped on the outside, of forming a perfect bond between the old and new portions of the dam and puddling the old dam where it had not been puddled before; also the removal of the silt would increase the capacity of the reservoir.

A barge 24x50 ft. was built and equipped with a 10-in. centrifugal sand-pump, belt-driven by a 200-hp. motor; a 3-drum hoist driven by 25-hp. motor; a 2-in. priming pump driven by a 10-hp. motor; and other accessories necessary for the operation of the barge.

It was necessary to build 8 miles of standard transmission line for 22,000 volts, from one of the coal camps west of the reservoir. This current is transformed down to 2,300 volts and carried to the barge on insulated cables supported by movable towers 14 ft. high. The 200-hp. motor operates at 2,300 volts but transformers are placed on the barge stepping the current down to 210 volts for lights and the other motors. Twelve pontoons were built to carry the pipe line close to the barge. The pipe used consists of 300 ft. of 10-in. standard rolled steel pipe, 500 ft. of riveted steel pipe with flanges and 1,000 ft. of riveted steel pipe with slip joints.

After the dredge was in operation it was found that the material would not cave and readily slide toward the nozzle and that to run the pump to capacity some method of bringing material toward the nozzle was necessary. Sluicing with water by gravity was first tried. A hole was excavated 16 to 20 ft. deep with the large pump assisted by a high pressure jet from the small pump. Then a stream of water, about 15 sec.-ft., was turned into the hole. As long as this water was running through silt and sand it sluiced very readily but when a layer of clay was encountered cutting ceased and it became necessary to trench with shovels before the material began to sluice again. While this trench was being cut, the pump would be handling little or no solid materials and it was difficult to hold the clear water in the forms. Various scrapers were then tried that would cut through the blue clay rapidly and also drag it into the nozzle. A scraper was designed that would peel off a layer 2 or 3 in. thick of any material over which it would run, and was so designed that when it was loaded to capacity the cutting blade would automatically be lifted and the load pulled into the suction nozzle without further cutting. This scraper drags in from 1 to 6 cu.yd. at a trip depending on how the material caves in front of it.

It was found that some of the material would stand with a vertical face though the cut would be 20 ft. deep and the only way it would cave would be to undermine it. If the bottom layer happened to be sand this undermining could be done very readily with water, but if it happened to be clay, water had little effect on it. A modified road plow was bolted onto the side of the scraper in such a fashion that as the scraper was being drawn back empty the plow would turn out a furrow

from under the cliff whether the material was clay or sand and generally after two or three trips with the plow the bank would cave.

The method of operation has been to lay out the silt in areas 100 ft. wide and 500 ft. long and construct a sluicing-ditch back and forth across this area (Fig. 2). The dredge was started at one side and moved as the material was excavated. The sluicing is done in a trench perpendicular to the direction of the scraper. This gives a maximum fall for the water and allows the material caved by the scraper as well as that caved by sluicing to become thoroughly mixed with water before being brought to the nozzle (Fig. 3). As the scraper comes to the nozzle, the nozzle is lifted by the operator and the hole underneath is filled with the scraped material. Then while the scraper is going back after another load, the nozzle is worked up and down and gradually clears out the hole for the next scraperful. This method does not choke the line with mud and gives an even flow of solids. The sluice water runs toward the nozzle and is carrying solids continually. A dike is maintained between the barge and the end of the nozzle in order that clear water may be available for the small priming pump and also to confine water so that all sluiced material will settle where either scraper or sluiced water can reach it. A small dike is also

FIG. 3—SECTION PIPE AND SUMP FOR SAND PUMP

maintained between the area being scraped and the one previously scraped out to confine the water within the area accessible to the scraper. This dike is removed when the dredge is ready to be moved to a new location. After one area 100 ft. x 500 ft. has been excavated the dredge is floated into the pit and a new land opened up.

Settlement of Pumped Material—Where the material is used to build up a layer 27 ft. wide on the outside of the dam a wooden form is used on the outside consisting of two 2 x 12-in. x 16-ft. boards bolted to two 2 x 4-in. x 2 ft. 6-in. long uprights spaced 4 ft. from the ends. These forms are lapped and held by three pipes which are old boiler flues cut in 5-ft. lengths. These pipes are driven into the ground a distance of 2 ft. No bracing is used on these pipes except at the lower end where a pool of water is held to aid in the settlement of the extremely fine particles. The tail water from the outside is run back into the reservoir

through a 24-in. tile placed through the north extremity of the dam when it was constructed. When the form is filled the pipes holding the forms are removed and the boards are placed on the filled portion 4 ft. from the edge. A little straw is placed where the board rests on the sand and an embankment is thrown against the form with a railroad wing plow pulled by horses. This prevents the water from cutting under the boards. This outside form is 2,700 ft. long and six men are employed to watch it to prevent leaks and to turn the current when it runs toward the form. About five days are required to pump the form full and two days more are required to change the forms and plow the embankment against them.

On the inside where the fill is made with a 1 on 10 slope no wooden forms are used but a dike is thrown up with the wing plow and only two men are employed to watch 2,500 ft. The water, when the material is pumped inside, after all the solids are settled out, gets back into the sluicing-ditch and is used again.

The delays so far have not been very serious or have not added greatly to the cost. The main causes of delays are breaks in the sluicing-ditch, breaks in the forms on the outside and the choking of the nozzle with lumps of coal and trash. When the nozzle is choked the sluicing water is cut down and the speed of the pump is reduced to the minimum and the nozzle is raised as high as permissible without losing the priming. The operator then gets down and removes the material caught on the screen either with his hands or

FIG. 4—WASTEWAY AT END OF FORM FOR DOWNSTREAM FILL

feet, sometimes using a bar. After it is clean, the nozzle is lowered and the pump speeded up. The advantage of this method is that the priming is not lost.

A log of operations is kept and there is not lost during the 9-hour day over an average of $\frac{1}{3}$ hr.

The cost of the entire plant ready for operation was \$41,084.91. The cost of labor, power, repairs and all other expense incidental to the moving of the earth has been \$25,504.52, and the total yardage removed to date has been approximately 210,000 cu.yd. at a cost of 12.14c. per cubic yard. Figuring the cost of plant into the work, the total cost to date would be 25.83c. per yard.

The cost of reinforced concrete averaged \$17.50 per yard and the cost of the rock riprap averaged \$7.50 per cubic yard laid on the face.

Through the Reclamation Country

By F. E. Schmitt

Associate Editor, *Engineering News-Record*

A SERIES OF ARTICLES on Federal Land Reclamation starts in *Engineering News-Record* in this issue. It will give a history of the twenty-one years of government irrigation, state the many problems of operation—engineering, agricultural and financial—analyze the various complaints that are being so emphasized by those who are seeking a reform of the current law and methods and seek to present some views as to a constructive policy in the future. Through it all will run the evident theme that irrigation, from planning, through construction to operation, is a continuing engineering problem.

As a part of the preparation of the series Mr. Schmitt is now traveling through the West, visiting irrigation projects, studying developments and interviewing builders, operators and settlers. He is writing this series of letters of running comment on the situation as he sees it on the ground. These are not the final result of his trip but they will serve to acquaint our readers with the actualities of reclamation as revealed to an unprejudiced investigator.

This is the fourth letter. The first appeared in the issue of October 4.—Editor.

Portland, Ore.

Complaints Against Increased Costs—A common matter of complaint by farmers on the reclamation projects is the high cost of the works, and more particularly the excess of cost over what was originally estimated or (as they say) promised. This subject seems to have been a source of animosity from an early period.

A newspaper editor who has lived near the Uncompahgre Reclamation project for many years says that he saw the engineer's original memo giving \$22 as the construction cost per acre, with a safety margin. The project has cost \$70 per acre and may cost more if drains are built. He protested against the injustice of burdening the farmers with excessive construction costs and said that unforeseen troubles and costs should be borne by the government, just as a contractor sticks to his bid and puts the job through even at a loss.

In Idaho, on the north unit of the Minidoka project, a representative of the water users complained of the effect upon the farmers of what he called the wrong estimates of the engineers. He claimed that the first announcement of cost was below \$25 per acre, that later, on account of building laterals, the figure was raised to \$30, and that now it is \$42 because of expenditures for drains.

The facts are that in every case after a cost had been definitely announced each proposed increase in expenditure was discussed with the water users and carried out only with their approval; that the first plans for many projects contemplated building only the main supply lines; and that the data which answer complaints and criticisms like the above are available to the leading men among the farmers. The case of the Uncompahgre costs was fully dealt with by Arthur P. Davis in a statement presented before a congressional committee last winter. The Minidoka people know that their costs are moderate. Complaints against costs are repeated probably because they are convenient talking points rather than because they represent genuine grievances. The costs in all cases represent necessary investment to make the land productive.

Laterals and Drainage—From their early days the needs of the reclamation projects have expanded. Originally it was the plan of the Service to build in the way that most private or group irrigation systems had been built, that is, to provide the supply (storage or diversion) and main canals, leaving the farmers individually or in small groups to dig their lateral ditches. Even today most private systems are on this basis. But the government settlers needed to have the laterals brought to them. The Service therefore built canals up to each farmer's land. Even so, an occasional farmer complains because the government did not carry its ditch to some other point of his farm, that would suit him better.

Drainage became necessary later. It does not appear to have been foreseen in the original planning that continuous irrigation would raise up the ground-water contours and in time waterlog the lower points of the area. Drainage ditch construction has had to be undertaken on an extensive scale by the government. The drainage is being steadily extended on most projects, as the ground-water surface has not yet reached a stable level even after fifteen or twenty years of irrigation. Incidentally, exactly the same is true on private projects, and the South Side Twin Falls district, some distance west of Minidoka, is now busily engaged in drainage work, though it has been in operation for more than fifteen years and is underlain by hundreds of feet of fissured lava beds with free vent to the Snake River Canyon, along one edge of the area.

There have been some increases in cost due to unforeseen natural obstacles—as the construction difficulties of the Gunnison tunnel supplying the Uncompahgre project, which made the contractor abandon the work and required the Service to complete it—or due to changes in labor cost and the like. In some cases too, there has been unfortunate concentration of cost, as when the irrigable area was reduced by abandoning part of the land so that the remaining land was made to bear all the costs. But the reclamation farmer has not been burdened with the costs of waste or failure, as represented by the Jerome Reservoir in Idaho (private) or the Tumalo Reservoir in Oregon (State) both failures. The Reclamation Service has done its work well.

The aggregate fact is that irrigation costs are inevitably uncertain at the start, and that some misunderstandings may easily result herefrom. Again, however, private projects furnish parallels to the experience of the Reclamation Service. On the North Side Twin Falls project, says its manager, R. E. Shepherd, the original calculations of cost showed \$25, \$35 and \$40 per acre, respectively, for three successive divisions, and land was sold accordingly (this was a Carey Act project); but the actual cost, with accumulated interest, today stands at \$80 per acre, and on present sales this amount is asked.

Criticisms of Water Supply—There are some criticisms of inadequate water supply. This is a very natural subject for differences of opinion. The water required for good irrigation results depends on the soil, being greater for porous than for tight soil. In some districts it also depends on the salt content of water and soil, which may require excess water for leaching purposes. But in all regions it also depends on the farmer; he must give some extra attention and labor to use the water economically and to avoid waste by overflow. On the south unit of the Minidoka project, where all the water is pumped, the farmers' representatives claim that

they are hampered by insufficiency of water in July, and a specially careful and thrifty farmer said to me that, while his crops are good, he thought he could do considerably better with more peak-season water. Leaching is not required at Minidoka. On the face of the crop records this unit is producing as well per acre as neighboring irrigation areas, which rather opposes the claim of harm from water shortage. As the pump and canal capacity do not permit of increased flow, moreover, one might expect the farmers to be content with conditions, at least for the present. That they are not, seems to be merely another illustration of the unrest, not to say demoralization, created by the element of politics in reclamation.

However a vote of the farmers on increasing the supply was taken at Minidoka, a few weeks ago, under orders from Washington; the proposition was defeated. It may be that the farmer's good sense is getting the better of political quarrelsomeness.

Construction Costs in France

Paris Correspondence

A REPORT of the Federation Nationale Française du Batiment et des Travaux Publics has the following to say with regard to construction costs in France.

Construction costs are arrived at from the consideration of three principal elements—material and its transport, labor and general overhead.

Since 1914 prices of building materials in France have undergone important and frequent variations.

In the mass there was general and steady rise of material costs until 1920 when they reached their extreme height with a coefficient of increase (the quotient being the figure of 1914) between 4 and 5, on certain items even exceeding the latter figure.

A notable fall in the prices of many items was remarked in 1921 and continued progressively until the beginning of 1923, at which time the prices in general began to climb again, without however, having, as yet, reached the figures of 1920. This situation of 1923 is laid to two causes, the increase in the cost of combustibles and the high rates of foreign exchange.

In general, wages have undergone notable increases and overhead expenses have continually increased by reason of various forms of taxation which today apply to the contractor and construction engineer which hitherto had no part in the fiscal policies of the government.

Summing up, it was estimated that construction costs were 3.5 times as high as in 1914. Taking into consideration interest charges and the value of money in the financial market the owner of a rented building was justified in charging four times a pre-war rental, assuming that it was a new building with which he was dealing.

U. S. Weather Bureau Aids Rain Insurance

Many insurance companies have been working on the question of the risk involved in insuring entertainments such as fairs, fashion shows, ball games, balloon races, stock exhibits, etc., against poor gate receipts because of rainy weather. While rain insurance is a private enterprise, the U. S. Weather Bureau is called on to furnish data as to the frequency and amount of rainfall in given places at stated seasons, or otherwise to supply information that will aid rain insurance companies to estimate their risks and adjust their rates.

Modern Steel and Reinforced-Concrete Structures Survive Japanese Earthquake

Report of John W. Doty and W. W. Johnston, American Engineers, Gives Results of Survey in Yokohama and Tokyo After Disaster of Sept. 1

The first authoritative information regarding the condition of engineering structures after the earthquake and fire which destroyed portions of Yokohama, Tokyo and other smaller municipalities of Japan on Sept. 1 is contained in a report to the Secretary of State, Washington, D. C., prepared at the request of Ambassador Woods by John W. Doty, president, and W. W. Johnston, engineer, the Foundation Co., New York, who were aboard ship in Yokohama harbor when the quake occurred. This document, the source of the information which follows, adds a great amount of detail, based on personal observations of the two American engineers from Sept. 1 to Sept. 12 in both Yokohama and Tokyo, to Mr. Doty's diary published in "Engineering News-Record" of Oct. 4, p. 569.—EDITOR.

THE FIRST earthquake shock occurred at 11:57 a.m. Sept. 1, causing the greatest damage in an area of about 80 miles, north and south, and 65 miles, east and west, centering in the neighborhood of Yokohama. The quake at Yokohama seemed to be continuous for a period of from 40 to 60 sec., and was followed by repeated shocks of lesser intensity over a period of five or six days. About 700 shocks were counted during the first four or five days. A report issued by the Japanese Government on Sept. 4 stated that there would be at least an additional 300 shocks before the earth's surface would readjust itself.

Tokyo, the capital and largest city of Japan, has a population, including suburbs, of more than 3,000,000. It is about 18 miles from Yokohama, the seaport, which has a population of 423,000. Japan itself has a population of 56,000,000. The area seriously damaged by the earthquake contains about 4,500,000, or 8½ per cent of the total population.

On Sept. 3 Mr. Doty and Mr. Johnston began an inspection of the effects of the earthquake on various types of structures in Yokohama and Tokyo. From their joint diary of this trip the following excerpts are taken:

QUAKE'S EFFECTS IN YOKOHAMA

The sea walls along the waterfront at Yokohama were seriously damaged and portions of them overturned. The first structure of note was the bridge across the canal at the south end of the Bund. This was a modern riveted-steel structure about 100 ft. in length. The superstructure was not damaged but the wing walls of one abutment were broken and the approaches to the bridge had settled some 2 or 3 ft.

We walked along the Bund where all the buildings were completely destroyed and there were many fractures noticeable in the streets. The walls of the City Hall were standing but the whole inside of the building had been burned. The street was a mass of fallen electric service wires and at the junctions of the streets it was in places difficult to get through them. A large reinforced-concrete building of some six stories facing the end of that street had been completely

burned, but the concrete frame and floors appeared to be undamaged by either the earthquake or the fire. We passed the Chamber of Commerce, a brick building of 3 or 4 stories with a clock tower 100 ft. high. This building was destroyed by fire, but the walls and tower were standing.

The Yokohama Specie Bank, a three-story structure 200 ft. square, equipped with steel fire doors and shutters which had been closed prior to the fire from the outside, appeared to be the only building in this part of the city which was intact. It was subsequently rumored that the building had been destroyed inside by

DAMAGE ALONG THE BUND, YOKOHAMA

fire which had gained access through the roof. This we were not able to verify.

We passed along the main street where most of the structures were of the older type with brick walls and probably wooden floors and partitions. All of these buildings were totally destroyed and most of them appeared to have collapsed prior to the fire, and no wood or other burnable material was to be found amongst the wreckage. This would indicate the tremendous heat of the fire. There were two small buildings of modern reinforced-concrete construction whose general framework seemed to be intact but the contents had been totally destroyed by fire.

The bridge in front of Sakuragicho Station, which is a modern structure, seemed to be in fairly good condition, although the street approaches had settled. In this vicinity there were also large fractures in the ground, some of which were 18 in. wide, running at right angles to the canal and parallel to the main shore

of the bay a half mile away. This confirms the statement of some eye-witnesses that these fractures were parallel to the crest of the land waves which were plainly visible.

Crossing the bridge we arrived at Sakuragicho railway station. A few of the walls were standing but the structure was for all practical purposes, totally destroyed and all the district around the station had been not only destroyed by the earthquake but also by the subsequent fires. Not even a wall was standing, but the brick retaining walls of the railroad embankment seemed to be intact.

Proceeding along the main road to the Yokohama station it was remarkable that the only two buildings remaining intact, a modern type reinforced-concrete and an old fashioned brick building, are side by side and show no indication of having been damaged by either earthquake or fire, although they are surrounded by complete destruction by both. Back of these buildings and against the hill some two blocks distant, the gasometer was uninjured, although the pumping station directly adjoining it was damaged by both the earthquake and fire, and all the other scattered houses along the hillside had been burned. In this section we saw two unburned street cars. Most of the main Yokohama Station had collapsed and had been damaged by fire although some of it was standing.

Under the bridge where the railway crosses the street at the Yokohama station there were many large fissures in the ground and beyond the bridge the street was practically covered with fissures. A 20-ft. embankment on the branch railway had been shaken down and the rails and ties remained suspended. Several structures between the railway and the waterfront remained standing and were apparently uninjured. It cannot be too strongly emphasized that, with the exception of those buildings named and a very few damaged dwellings in the foreign settlement on the Bluff, all of Yokohama has been completely destroyed.

Beyond Yokohama Station along the road parallel to the railway tracks a great many fissures occurred on the streets and practically all the distance to Tokyo. Along this road through Kanagawa and to Kawasaki, a distance of 2½ or 3 miles, all the buildings were destroyed by the earthquake and fire. The railway bridge out of Yokohama, which was constructed of deck plate girders spanning the canal was destroyed by fire. The girders sank vertically about 6 in. by the heat. The ties were completely burned and the rails, although remaining connected, were buckled, resembling a letter "S." This bridge was a two-span 4-track structure about 75 ft. long.

The fire ended very abruptly at a narrow street not more than 20 ft. wide. Along one side of this street the light frame houses had been completely burned, while across the street, although the houses of a similar type had collapsed into a mass of matchwood, they had not caught fire. From this point to the Rokugo River, about half way between Yokohama and Tokyo, there had been no general conflagration and comparatively few of the houses, which were all of native type, had collapsed in the earthquake, although many had been shaken and damaged.

Two railway bridges over the Rokugo River had been damaged but could be readily repaired. The wooden highway bridge on pile bents had been severely damaged by the sinking of two of the pile bents, but

remained passable for foot traffic. On each side of and parallel to the river, fissures in the ground were noticeable for 200 ft. from the water's edge.

From the Rokugo River to Shinagawa and beyond, almost to Shiba Park in Tokyo, the damage visible from the road was comparatively small.

At Shiba Park it became evident that although certain districts in Tokyo had not been seriously damaged, in a large part of the city the destruction had been as complete as in Yokohama, and from Shiba Park to the Imperial Hotel many fires were still burning. We arrived at the Imperial Hotel at 7.45 p.m. and found it undamaged but in total darkness. We learned that the American Embassy had been burned and that the Ambassador had established headquarters at the Imperial Hotel.

DAMAGE IN TOKYO

In Tokyo an area of approximately 30 sq.mi. was completely destroyed. In this area a small portion known as the Marunouchi district, which included a number of large bank buildings, new office buildings and the Tokyo central station, and a section which included the Peers' Club, the Imperial Hotel and most of the various government buildings were only partially destroyed. That part of the city outside of the completely destroyed districts was severely damaged by the earthquake and isolated fires probably to the extent of 25 per cent of its value. It is estimated that between 60 and 70 per cent of the total property value of the city of Tokyo was destroyed.

The buildings which existed in Tokyo can be classified under five heads: (1) Native frame houses constructed principally of pine; (2) small structures with brick walls and wooden interiors; (3) larger government and office buildings of heavy exterior and interior brick walls, with wooden floors; (4) modern buildings of four to eight stories with structural steel frames and fireproof or slow-burning walls and floors; (5) reinforced-concrete buildings of from two to eight stories with concrete floors, exterior walls of concrete, or veneered with masonry or stone. Probably at least 80 per cent of the buildings in the city were of frame construction, 15 per cent of brick and frame, and 5 per cent of the remaining three types referred to above. Buildings are limited by law to a height of 100 ft.

In the area totally destroyed by the earthquake and fire all the buildings, irrespective of classification, were destroyed, the framework only of a few isolated reinforced-concrete buildings remaining standing. In a small unburned area from the government buildings near Hibiya Park to the Marunouchi district, with comparatively wide streets and a number of open spaces, containing principally massive or modern buildings of substantial construction, practically all the structures were more or less damaged by the earthquake, but only a few of them collapsed, although a number of them were burned. This area was saved from the general conflagration principally by a change in the direction of the wind, which caused the fire to turn back just before it reached this district.

Our observation of some of the buildings which remained standing was in general as follows:

Imperial Hotel—The building was standing practically uninjured. Following the moat toward the Marunouchi district from the Imperial Hotel, the Life Insurance Co.'s office building, a modern structure, was

not damaged by the earthquake and fire, although directly behind it a large three-story frame structure had burned.

Police Headquarters—This heavy governmental type of structure had withstood the earthquake but had been gutted by fire some time later.

Imperial Theater—The roof of this building, a modern structure of its type, collapsed on the first shock, and fire, which started from within, burned the whole interior but most of the exterior walls are standing. This example shows the necessity, in earthquake zones, of strongly buttressing the side walls and practically bridging the roofs in theaters or similar structures with large roof spans. If a large number of people had been in the theater at the time of the earthquake probably none would have escaped.

The Kaikuan—This structure, known as the Palace Restaurant, next beyond the Imperial Theater, was a modern steel-frame structure of six stories. The shock

from the Marunouchi Building the Tokyo Central Station and Hotel, a massive brick-and-steel structure of four stories, was not seriously damaged by either the fire or the earthquake. The Kaijo Building was a modern six or seven story office building, having structural steel frame and brick exterior walls. The walls of this building were shattered throughout and in places had fallen to the ground, exposing the steel work. This building did not take fire. The Industrial Bank Building, probably the most modern building of its type in Tokyo, which had just been completed, the frame being either of reinforced-concrete or steel (our impression is reinforced concrete) seemed to withstand the earthquake without any damage whatsoever, even the large windows being unbroken.

Bank of Japan—This structure, outside the Marunouchi district and across the canal, is of old type, with heavy masonry walls. The fire doors and shutters were closed and most of this building seemed to be undam-

COLLAPSED PIER IN YOKOHAMA HARBOR

WAREHOUSE DAMAGED AS PIER SUBSIDES

of the earthquake caused the outside walls and the interior partitions of the third story only to shatter and fall, leaving every steel column on that floor exposed. The lower two stories and the upper three stories appeared to be only slightly damaged. The exposed steel columns of the third floor were bent out of plumb, however, and the upper three stories were thrown on an offset of approximately 15 in. from the line of the lower two stories. The building had not been damaged by fire.

There were a number of structures beyond the Kaikuan which were only slightly damaged by the earthquake and fire. These were principally three or four stories in height, of ordinary brick construction. Nearby, the structural steel framework for a new building which was being erected had collapsed and carried down with it some 200 workmen. In erecting steelwork where earthquakes are liable to occur each floor should be riveted and sufficient sway-bracing should be embodied in the design to make the frame of the building independently strong.

N. Y. K. Building—A new, modern, 6-story structure, which had just been opened, was of structural steel with very heavy masonry and brick walls. The exterior walls enclosing the second story were fractured by the earthquake, and cracks in the wall formed a distinct X in each panel running diagonally from top to bottom. The first story and the stories above the second appeared uninjured.

Marunouchi Building—A modern steel-frame office building of six or seven stories occupied an entire block. Although the building stood, some of the outside veneer was fractured or had fallen off. Across a wide plaza

aged by either the earthquake or fire. It is the only building of importance in the totally burned zone that is now standing in usable condition. All other structures in its vicinity, including the Mitsui Building and the Mitsukoshi Department Store, were burned, but the frames of a number of modern structures of reinforced concrete type remained standing, although the buildings had been gutted by fire and, in many cases, the exterior walls thrown down. In the greater portion of the 30 sq.mi. of the totally destroyed area, however, few frames or walls of any description remain standing.

Most of the small canal bridges of modern construction seem to be little damaged.

In reconstructing Tokyo a proper building code should be adopted to minimize, as far as possible, damage by earthquake and, what is much more serious, the spread of fire, as the destruction by fire was far greater than by the earthquake.

Most of the isolated government buildings of heavy brick type of construction, located south of the Imperial Palace Grounds and west of Hibiya Park, were not seriously damaged by the earthquake or fire.

Interview with John W. Doty

In an interview with a representative of *Engineering News-Record* last week, Mr. Doty amplified some of the points covered in the foregoing report. He emphasized the fact that the earthquake alone was not responsible for the widespread damage done in Yokohama and Tokyo. The toll both in lives and in property damage was greatly increased by the fire which swept over the stricken cities after the shock. In any program of

reconstruction, therefore, Mr. Doty believes that the provision of fire zones and the widening of the old narrow, twisting streets assumes an importance equal to the building of modern engineering structures of reinforced concrete or steel, designed to resist earthquake shock.

"I believe I am well within the facts," said Mr. Doty, "when I state that 95 per cent of the real engineering structures of modern design in Japan withstood the earthquake. Many of these structures were later gutted by the fire, but, regarded solely from the structural standpoint, they proved adequate. In some cases, of course, the curtain walls on these modern structures were shaken down, but the main framework stood up and the damage was comparatively slight. With our present-day knowledge of building design and construction methods, we can produce structures for which I would have no fear in the event of a repetition of the earthquake shock of Sept. 1."

The big lesson to be learned from Japan's disaster, according to Mr. Doty, is the necessity of having the columns, walls, and floors of structures tied firmly together, forming, in effect, a rigid cage.

"Many people," Mr. Doty continued, "have a false conception of the action of an earthquake. It is not a single shock, like a quarry blast, for example, but is a series of violent oscillations extending over a considerable period—in the case of the shock at Yokohama from 40 to 60 sec. On a building whose main elements are not well tied together the effect of a quake is like that of a battering ram. During the first few seconds, if the structure be improperly designed, gaps will be opened between the floors and side walls. Into these openings will fall material shaken down from above. Beams, girders and flooring moving back and forth rapidly like the piston in a steam engine literally batter down the side walls of a building. This result, of course, cannot be produced if the parts of the structure are integral. The action on a building, during a quake, is comparable also with that of cracking a whip. The structure is actually a cantilever with its top end being snapped back and forth. It is necessary, therefore, to design the structure to resist great shearing stress."

In the case of reinforced-concrete structures Mr. Doty believes that resistance to earthquake shock can best be accomplished by casting the walls and columns as a unit, in this way tying the structure together. Japan's building laws at present limit the height of structures to 100 ft. Mr. Doty considers this restriction reasonable and would even go further, by reducing the figure to 75 or 80 ft., resulting in a building with a maximum of about six stories.

Japanese cities inherited from the days of the old empire flimsy structures of wood and brick, often covered with a heavy tile roofing. Unprovided with sway bracing, the walls during a shock would spread, allowing the roof, with its heavy load of tile, to collapse. It is probable, Mr. Doty believes, that these old types of structure will not be rebuilt. In replacing the smaller residence buildings he sees an opportunity for the effective use of asbestos shingles for roofing.

It is Mr. Doty's opinion that the results of the earthquake indicate that for moderate sized structures reinforced concrete is well adapted to resist shocks, while for the larger office buildings and other commercial structures either reinforced-concrete or modern skeleton steel-frame types will be found adequate. For the

smaller structure he pointed out substantial economies in favor of reinforced concrete as compared with structural steel.

There is no doubt in Mr. Doty's mind that in the rebuilding of Yokohama and Tokyo modern methods of design and construction will be largely employed. It is significant that the Japanese government has ruled that only temporary structures may now be rebuilt without a permit. Due to rapid commercial developments land values in the larger Japanese cities have been increasing at a rapid rate, making uneconomical the low, old-fashioned structures in which Japanese business was housed. This will mean, it seems probable, taller and stronger structures.

If any larger-scale building program along modern lines is adopted, it is certain that Japan will call upon other nations, the United States and England particularly, for modern construction equipment and supplies. While the Japanese, during the last generation or two, have made substantial progress in modernizing engineering design, they are not equipped, as is the United States, with the machinery and tools to prosecute work according to American construction methods. The hazards of earthquakes, Mr. Doty believes, need not be regarded as a bar to the profitable investment of foreign capital in Japan, for the recent disaster has demonstrated conclusively that modern methods of building design and construction can be depended upon to produce structures that will stand up if adequate attention to the structural features of the problem is supplemented by intelligent planning to prevent the spread of fires.

Another A.I.C.E. Ethics Committee Case

AT A meeting of the American Institute of Consulting Engineers held recently, the Committee on Professional Practice and Ethics presented its report on a hypothetical question known as Case No. 21. The two phases of this Question and Answer, as reported by F. A. Molitor, secretary of the Institute, are reproduced herewith.

Question 1—When a member of the Institute has a partner who is not a member of the Institute and that partner, without his knowledge or consent, conducts himself otherwise than in accordance with the Code of Ethics of the Institute, what duty, if any, does the member of the Institute have to his brother engineers and the public with respect to the conduct of his partner? **Answer**—It is the duty of the member of the Institute to induce his partner to shape his conduct so as to harmonize with the ethical principles which the Institute has laid down for the conduct of its members, and failing to do so he should consider it his duty to sever his connection with either his partner, or the Institute.

Question 2—When an engineer, being a member of the Institute, conducts his professional practice through a professional service corporation, and representatives of that corporation, not under his direct control, conduct themselves, and the business of the corporation, otherwise than in accordance with the Code of Ethics of the Institute, what duty, if any, devolves upon the member of the Institute with respect to his brother engineers and the public? **Answer**—It is the duty of the member of the Institute to induce the responsible representatives of the professional service corporation so to conduct themselves and the business of the corporation as to harmonize with the ethical principles which the Institute has laid down for the conduct of its members, and failing to do so he should consider it his duty to sever his connection with either the professional service corporation or the Institute.

Industrial Waste Pollution Conference a Success

Held at Philadelphia Under Joint Auspices of
Engineers Club and Local Section,
Am. Soc. C. E.

A WELL-ATTENDED conference on the pollution of streams was held on the afternoon and evening of Oct. 16 at Philadelphia, under the joint auspices of the Philadelphia Engineers Club and the Philadelphia Section of the American Society of Civil Engineers. Among the hundred or so at the conference were many well-known sanitary engineers from New England and the Middle Atlantic States and also a goodly representation of conservation commissions and of the oyster, paper, and other industries. Among the topics on the program were federal and state control of pollution, stream pollution as affecting navigation, industrial wastes in relation to water supply, stream pollution at Philadelphia, and coal mine drainage contamination of water supplies.

The stream pollution investigations of the United States Public Health Service were briefly outlined by Surgeon W. H. Frost, who stated that so far as he can judge the chief interest now lies in the organic pollution of streams and resulting nuisances, but added that the time would doubtless come when consideration could be given to the effect of distant bacterial pollution on public water supplies. George T. Hammond, consulting engineer, Brooklyn, said that perhaps sanitary engineers are chiefly interested in the effect of stream pollution upon the bio-oxygen demand especially in connection with sewage-works. H. P. Eddy, consulting engineer of Boston, spoke of the tremendous effect of very few industries upon the character of the streams. He mentioned the three rubber reclaiming plants at Akron, Ohio, which together contribute 117 lb. of solid wastes to the river for each 100 lb. contributed by the city sewage.

Government Control—In the course of his presentation of Government Control of Pollution, C. A. Emerson, Jr., formerly chief engineer of the Pennsylvania Department of Health and now associated with the Philadelphia office of Fuller & McClintock, consulting engineers, remarked that about 80 per cent of the state health departments of this country now have sanitary engineers. Mr. Emerson spoke approvingly of the methods of control of stream pollution employed in Great Britain, where joint commissions or river boards having charge of entire drainage districts prove useful. These boards are generally large, their membership extending to 25 or 30, and the members being elected by the local governing boards of each municipality in proportion to population. There are similar boards in Germany, but some of these, like the Ermscher District Board, have representation by industries, as well as by municipalities. There is a notable difference between available machinery for the control of stream pollution and health matters in Great Britain and Germany, on the one hand, and in the United States on the other. Whereas the two former countries have national health departments, we have none in this country. Mr. Emerson expressed the opinion that any centralized control of stream pollution in the United States would not be welcome if it were designed to

set aside state agencies, but thought that some means might well be devised for federal co-operation in stream pollution control.

An outline of "The Powers, Duties and Policies of the Sanitary Water Board of Pennsylvania," presented by W. L. Stevenson, chief engineer, Pennsylvania Department of Health and secretary of the board just named, was an outstanding feature of the conference. (An abstract of Mr. Stevenson's paper follows on p. 684.)

Sanity and Adaptability—The discussion on Mr. Stevenson's paper was opened by H. P. Eddy, of Boston, who said the code goes a long way in the direction of sanity in the control of industrial wastes. In general, there should not be an attempt to compel each industry on a stream to comply to one standard or any industry always to try to attain the same standard for that industry. State control should not establish arbitrary rules or standards, but instead should require cessation of pollution without saying how, since if an attempt is made by the state control body to define methods of stopping pollution and the methods proposed are followed and results are not satisfactory, there may be serious embarrassment to the control body.

By way of illustration of elasticity of means of preventing stream pollution through variation of the methods employed to suit temperature and river stages, Mr. Eddy stated that a tannery in Massachusetts employs varying degrees of treatment at different seasons of the year to meet fluctuating conditions. At times of low stream flow, treatment is supplemented by dilution from water stored for the purpose. When both treatment of the wastes and stream dilution are not sufficient or water enough for dilution is not available, then, as has been done this year, the stream is dosed with nitrate of soda in order to increase its available oxygen.

Col. George A. Johnson, consulting engineer, New York City, complimented Pennsylvania on being the first state to attempt the control of pollution of streams from their source to their mouth. He remarked on the fact that if 100 per cent treatment of industrial wastes were required some industries might be financially ruined or driven from the state. Robert S. Weston, consulting sanitary expert, Boston, spoke a word in behalf of manufacturers, most of whom he thinks are favorably disposed toward the prevention of stream pollution. In support of the latter opinion co-operation of owners of industrial plants in Rhode Island was cited.

George W. Fuller remarked on the great difference between theory and practice in government control. The first British Rivers Pollution Act of the seventies was on the statute books some fifteen years before much was done to comply with its requirements. Little was accomplished until the rivers boards mentioned by Mr. Stevenson were created.

Progress resulted when a balance was established between what is being done by the municipalities and by the industries to stop stream pollution. Mr. Fuller stressed the point that consideration should always be given to whether money could be better spent for the prevention of river pollution or for some other public purpose, like the building of parks and playgrounds or providing other recreational facilities. Speaking for the second time on Mr. Stevenson's paper, H. P. Eddy stated that in stream pollution control the rule of

reason must be followed. J. F. Jackson, engineer, Connecticut Board of Health, also emphasized the fact that success in stream control depends upon the wisdom shown in both drawing and enforcing regulations.

Dr. W. H. Frost, surgeon, U.S.P.H.S., referring to remarks by Mr. Emerson to the effect that there was a diversity of laws regarding stream pollution in the different states, said that the administration of the laws was far more uniform than the laws themselves, this being due to the fact that the administration is in charge of men who are working along common lines arrived at in part by the conferences of state sanitary engineers that are held each year.

Remarkable New Filter—The "Stream-Line Filter" was described in a paper by George W. Fuller, consulting engineer, New York City, as "one of the most interesting exhibits at the shipping, engineering, and machinery exhibition at Olympia, London, last month." This filter is the invention of Dr. H. S. Hele-Shaw, president of the British Institution of Mechanical Engineers last year. It consists of a pack of specially prepared paper held together between two press-heads. The liquid to be filtered is forced through the filter between the sheets of paper and the pressure is varied according to the character of the liquid or of the material which it is desired to abstract. An abstract of Mr. Fuller's paper will appear in a later issue.

Navigation—"Stream Pollution as Affecting Navigation" was the title of an address by F. C. Boggs, colonel, Corps of Engineers, U. S. A. Federal control comes through the interstate commerce clause of the constitution and is administered by the Corps of Engineers, Col. Boggs said. Navigable waters are construed as being any waters that will float logs. In the control of navigation the army engineers have no jurisdiction over pollution as such. What they do control is (1) solids which may impede or cause deposits that will impede navigation and (2) semi-solid matters injurious to shipping. It has been held that (2) does not include oil but Congress could legislate on that subject. In fact it has legislated so far as New York harbor is concerned where oil discharges are under the control of the supervisor of the port. The present oily wastes from ships in New York harbor are pumped from the ships and the oil is recovered by a private company. There is need for a separator available for use on each ship.

As to remedies for the oil nuisance, Dr. Frost said that the enactment of laws is first thought of but if enacted who would enforce laws? Again the first thought is the federal government. It is deeply interested, Dr. Frost said, but he did not suggest that it could undertake the work. He did say, however, that it appears that anti-pollution measures, like charity, should begin at home, making it the principal duty of the federal government to control interstate and international oil pollution. Too great a burden must not be thrown upon industries for ultimately this burden will be borne by Mr. Private Citizen.

Russell Suter, senior assistant engineer, New York Conservation Commission, Albany, N. Y., said that there had formerly been much trouble from an oil refinery at Olean, N. Y. The Standard Oil Co. put in a plant for preventing stream pollution which is reported to be profitable. Other oil wastes, Mr. Suter said, are not so much different as would be thought and

probably they also could be successfully treated. It has been asserted that oil wastes injure fish. Mr. Suter said he was not sure as to this, except that he had reason to believe that they do not injure shell fish. Morris R. Sherrerd, chief engineer, Department of Streets and Public Improvements, Newark, N. J., cited the Passaic River which was formerly much used for boating, but which sewage pollution had made useless for that and many other purposes. The expenditure of \$20,000,000 by the Passaic Valley Sewerage Commission to prevent the pollution of this stream may perhaps restore boating to the river.

Pollution by automobile oils contributed to sewers from public and private garages was the subject of considerable discussion during the conference. The consensus of opinion seemed to be that this is a serious matter in many cities. In Philadelphia a city ordinance requires intercepting traps to keep the oil out of the sewers. There seemed to be some difference of opinion as to the effectiveness of this ordinance.

Public Water Supplies—A review of data on industrial wastes in relation to water supply, collected by a committee of the American Water Works Association, and presented at the recent Detroit meeting of the association, was presented by Almon L. Fales, of Metcalf & Eddy, Boston, chairman of the committee. The data show that some 250 water supplies widely distributed in the United States and Canada are affected by industrial wastes, and that of these 138 are in Pennsylvania alone. There are some 25 different kinds of industrial pollution. Over 100 water supplies are affected by mine drainage. The whole matter of control here should be considered from the broad viewpoint of public welfare. Investigation should precede legislation.

In discussing this paper, R. S. Weston said that the committee has made clear that it is not yet possible to satisfactorily treat all classes of industrial wastes. For instance, this has not yet been found possible with the sugar factory wastes in Cuba, which discharge into small or almost dry streams; also creamery wastes. We are still in need of technical as well as legislative and administrative progress. Mr. Weston said his own leanings are toward rivers boards working in co-operation with industries. Such co-operation is being obtained in Rhode Island through the work being done by Stephen DeM. Gage and the Rhode Island Board of Purification of Waters.

In a paper on "Stream Pollution in Philadelphia" Maj. J. A. Vogleson, chief engineer, Bureau of Surveys, said the problem of industrial wastes is inseparable from that of the general sewage of the city since the industrial plants are scattered throughout the city and discharge into the sewerage system. There are 162 outlets discharging into the Schuylkill and Delaware Rivers. Many years ago an intercepting sewer along a portion of the Schuylkill diverted sewage below the water intakes on that stream and later on other interceptors were built and some are now under construction for the further diversion of sewage from the tributaries of the Schuylkill and Delaware and for its delivery to three treatment plants. As an illustration of the progressive pollution of the Delaware River, Maj. Vogleson stated that in examining samples of the raw water taken from the Delaware River before filtration there were employed successively 1 c.c., 0.1, 0.01 and now 0.001 c.c. The first of the large sewage treatment

plants included in the plan adopted in 1916 for cleaning up the rivers, construction on which was postponed by the war until 1921, is about ready to go into operation. This includes 32 Imhoff tanks located about two miles below the mouth of Frankford Creek.

A striking example of the damage to sewers sometimes done by industrial wastes was cited by Maj. Vogleson. About 1,700 ft. of invert of a concrete sewer was ruined within three weeks of the time that there began to be discharged into it some heavy acid wastes from an industrial plant. This sewer is of the basket section type, equivalent in cross-sectional area to about a 7-ft. circular sewer. The invert to a width of some 30 in. has been badly damaged, the acids in some cases penetrating to a depth of 7 or 8 in. It is estimated that it will cost \$70,000 to repair this stretch of sewer.

Coal Mine Drainage—In a paper on "Coal Mine Drainage Contamination of Water Supplies," J. W. Ledoux, consulting engineer, Philadelphia, reviewed the problem, particularly as it is presented in Pennsylvania, and outlined some possible means of treating mine drainage. This paper followed somewhat the same general lines as the one presented by Mr. Ledoux some months ago before the Pennsylvania Water Works Association, as abstracted in *Engineering News-Record*, April 19, 1923, p. 698. The possibilities of using barium oxide or hydroxide for the purification of coal mine water were discussed by Mr. Ledoux who concluded as the result of his investigations that this is the only satisfactory chemical to use and that while the cost would be prohibitive without the utilization of the byproduct—barium sulphate—yet by such utilization it would be practicable. Mr. Ledoux said: "With an average mine water containing over 2,000 p.p.m. total solids and over 1,000 p.p.m. sulphate it would require in the neighborhood of $7\frac{1}{2}$ tons of barium oxide per million gallons, and there would be about 13 tons of barium sulphate as a byproduct."

In discussing this paper, R. C. Bardwell, of Huntington, W. Va., said that when legislation against water pollution by oil wells in Kansas was enacted he was told that nothing would come of the legislation if its enforcement was likely to be a handicap to a basic industry of the state. The legislation proved to be of no effect. This would be the case with any legislation against coal mine drainage, Mr. Bardwell said. He urged that consideration should be given to the burden placed upon water users and water consumers by industrial wastes, and stated that it has been estimated that a group of Ohio River steam plants are burdened with an expense of \$2,000,000 a year on account of stream pollution. How these evils can be corrected has not yet been determined. Co-operation seems to be the most promising way. Self-help in this direction is illustrated by what one railway did in Illinois. It stored water when it was usable against the time when it would be bad.

Terminal Engineers Hear Weather Talk

The Municipal Engineers of the City of New York at their meeting Oct. 24 were given an address on the work of the weather bureau and its relation to the welfare of the public, entitled "Is It Going to Rain?" by James H. Scarr, meteorologist of the U. S. Weather Bureau in charge of the New York district.

Pennsylvania Sanitary Water Board: Powers, Duties and Policies

By W. L. STEVENSON

Chief Engineer, Department of Health, and Secretary,
Sanitary Water Board, Harrisburg, Pa.

Abstract of a paper presented to the Conference on Pollution of Streams Held by the Engineers' Club of Philadelphia and the American Society of Civil Engineers (Philadelphia Section) at Philadelphia, Oct. 16, 1923.

ONE of the principles of reorganization of the State government of Pennsylvania proposed by Governor Pinchot [on coming into office early this year] was the co-ordination of duties and authority having a common purpose and to that end "The Administrative Code," approved June 7, 1923, created in the Department of Health the Sanitary Water Board to have jurisdiction over stream pollutions of all kinds.

This Board consists of the secretary of health, as chairman, the secretary of forests and waters, the attorney general, the commissioner of fisheries and the chairman of the Public Service Commission. The powers and duties of the Sanitary Water Board include: (a) The administration of the laws of the Commonwealth prohibiting the pollution of the waters of the State; and (b) the study, investigation and reporting upon ways and means of eliminating and preventing stream pollutions which are detrimental to the public health, the health of animals, fish or aquatic life or to the recreational use thereof.

The principal advantages to be obtained from vesting all the anti-stream pollution laws in a board instead of separate administration as heretofore are uniformity of policy and the classification of streams to provide for the several kinds of uses of the waters of the State and expediting action in cases involving the jurisdiction of the several departments concerned.

Fundamental Policies—The Sanitary Water Board has established a number of fundamental policies through the adoption of resolutions. The first of these resolutions approved certain policies of the Department of Health relevant to sewerage and stream control, including the following: (1) That streams which are used as sources of public water supply after filtration should, in addition to being reasonably clean, provide a raw water sufficiently low in organic and pathogenic bacterial content that it can be safely and reasonably economically purified for domestic purposes. (2) That streams which are used as sources of public water supply with only chlorination should be kept free from all artificial sewage pollution unless adequate assured long-time storage is used for the water supply and in such cases the sewage effluent should be adequately disinfected as a further safeguard. (3) Requirements made to restore sewage polluted streams, not used as sources of public water supply, or to maintain clean streams in a clean condition should be begun at the head waters and progress down stream. (4) Requirements made to protect sources of public water supplies should be, in general and subject to local conditions, begun at the first source of sewage contamination above the water-works intake and progress up stream. (5) The agreement between Pennsylvania and New Jersey establishing a "Uniform Policy as to Degree of Treatment of Sewage Discharge into the Delaware River" (see *Engineering News-Record*, Aug. 10, 1922, pp. 215 and 243).

Classification of Streams—A resolution of the Sanitary Water Board adopted Aug. 8, 1923, for Classification of Streams, is as follows:

Whereas, The degree of pollution of the waters of the State varies widely from the pristine purity of a small stream flowing through a virgin forest to the grossly polluted stream draining a valley given over to intense municipal and industrial development, and

Whereas, Such differences in condition and the present and probable future use of the streams must be recognized in determining the required degree of treatment of sewage and industrial wastes, and

Whereas, The natural powers of streams to inoffensively assimilate and dispose of polluting matters by dilution must be utilized so far as compatible with the general interests of the public in order to establish a practicable and economical program for stream control, therefore

Resolved, That the waters of the State be classified as follows:

Class A: Relatively clean and pure streams—streams in their natural state probably subject to chance contamination by human beings but unpolluted or uncontaminated from any artificial source, hence generally fit for domestic water supply after chlorination, will support fish life and may be safely used for recreational purposes.

Class B: Streams in which pollution shall be controlled—streams more or less polluted, where the extent of regulation, control, or elimination of pollution will be determined by a consideration of (a) The present and probable future use and condition of the stream; (b) the practicability of remedial measures for abatement of pollution, and (c) the general interests of the public through the protection of the public health, the health of animals, fish and aquatic life, and the use of the stream for recreational purposes.

Class C: Streams now so polluted that they cannot be used as sources of public water supplies, will not support fish life and are not used for recreational purposes and also from the standpoint of the public interests and practicability it is not now necessary, economical or advisable to attempt to restore them to a clean condition; and further,

Resolved, That all artificial pollution of Class A streams shall be prohibited and any sewage or industrial wastes on the watershed shall be treated to such a degree that the effluent shall be practically free from suspended matter, non-putrescent and disinfected and that recreational use shall not be sanctioned within prejudicial influence of water works intakes, and further

Resolved, That the degree of treatment of sewage and industrial wastes discharged into Class B streams shall be determined for each particular stream or portion thereof after consideration of the general interests of the public and the economics of the particular case, and further

Resolved, That sewage and industrial wastes may be discharged into Class C streams; provided, however, that such discharge shall not create any public nuisance or menace to health.

Clean Streams Must Be Kept Clean—This resolution establishes the policy that streams now relatively clean and pure shall be kept in that condition. No future pollution thereof will be permitted. It also recognizes that, due to existing intense industrial development on certain watersheds, the streams thereof have become so polluted that they are now totally unfit for use as sources of public water supply nor will they support fish life and hence are practically set aside for the disposal of industrial wastes. The cost of construction and maintenance of works for the abatement of the pollution of such streams will far exceed the value of the benefits to be derived by the public through their restoration to a clean condition. Therefore, efforts will not be made, at this time, to accomplish any more than the prevention of menace to the public health and creation of nuisance in streams which may be designated as Class C.

The majority of the larger streams draining developed areas will naturally be found in the middle group, designated as Class B. The resolution recognizes the natural powers of streams to inoffensively assimilate a certain amount of polluting matter and that the use of the scientific method of disposal by dilution is essential to the success of any program for stream control because of the economics of the problem. The usual requirement to be met in determining the pollution load which a stream can receive when considering disposal by dilution is the maintenance of the stream in a cleanly condition as measured by sight or smell. But when the Sanitary Water Board designates any stream as Class B it will also determine the degree of treatment of polluting matter and this will be based upon the use and condition of the stream both at present and in the probable future in order to compare the cost of treatment on the one hand with the value of the benefits to the public obtained through protection to sources of public water supplies, fish life and recreational use of the stream.

Co-operation Essential—The co-operation of municipalities and private persons and corporations with the State is essential to the success of the comprehensive program of

the Board for stream control and hence a resolution has been adopted authorizing the Secretary of Health to notify all municipalities on the watershed of any stream that has been classified as to the required degree of treatment of sewage. Thus each municipality along the classified stream will know that as the means for abatement of pollution are progressively installed from the headwaters on downstream, they will benefit by the expenditures of their upstream neighbors and in justice they must do likewise for other municipalities situate on downstream.

Existing law requires the issuance of a State permit before public sewers can be constructed and provides penalties for unlawful discharge of sewage; hence, the Sanitary Water Board in administering the law will both confer privileges and impose obligations upon municipalities. The board has established the policy that good faith must be shown by municipalities in complying with requirements of sewage permits before they are granted further privileges or are relieved from penalties. For extending the limits of cleanliness of streams whose headwaters are not now polluted, plans have been made to have such streams examined by State employees whose regular duty includes the traversing of them in order to ascertain the first source of pollution and thereafter, if the board shall deem it expedient, means will be adopted to secure abatement. In this way the cleanliness of headwater streams will be gradually extended and increase the available sources of public water supplies, benefit riparian owners along the banks and provide more clean streams in the State for the pleasure of the public who are learning the healthfulness and value of recreation in the open through camping, hunting and fishing.

Complaints Must Be Concise and Well Founded—Various state officials and departments are constantly in receipt of complaints from the public concerning pollution of streams or the destruction of fish. Occasionally these complaints are concise and well founded, but generally they are vague and indefinite. The board has therefore established the policy that only well founded and concise complaints will be considered. Forms are sent to complainants in duplicate for furnishing the data and the statements made must be sworn to. Upon receipt of the properly filled in complaint form charging violation of law against any person, firm or corporation, the copy thereof is sent to the respondent who is afforded opportunity to make abatement or to submit defense of the charge in the complaint. After consideration of the formal complaint and the respondent's reply thereto, an investigation is made and if violation of law found and abatement is not made, prosecution is instituted. The board has by resolution placed the matter of handling complaints relative to destruction of fish with the Commissioner of Fisheries, pursuant to Section 501 of The Administrative Code.

The magnitude of the task confronting the Sanitary Water Board may be seen when it is realized that 13 per cent of the 4,419 named streams of Pennsylvania have drainage areas of over 25 sq.mi. and an aggregate length of 13,000 mi. and, by proportion, it is probable that the total length of all named streams is about 100,000 miles. Also it is estimated that the total average flow in Pennsylvania streams is at a rate of about 2,600,000,000 gal. an hour.

The sources of pollution are innumerable, diverse in character and of both public and private origin: there are 974 municipalities in the State of which only one-half have public sewer systems from which sewage or sewage effluent is discharged to the streams; also many towns have storm drains to which sewage connections have been made and countless private sewers discharge sewage.

It has been estimated that stream pollutions may be caused from about 2,500 industrial places representing a capital investment of over \$1,000,000,000 and yielding products valued at over \$1,500,000,000 a year. Hence the solution of the problem confronting the Sanitary Water Board must be approached sanely and deliberately with recognition of the financial aspects, so as to successfully carry out in an orderly and logical sequence, a comprehensive, practicable program for stream control in the Commonwealth of Pennsylvania.

A Half Day with Karl Imhoff

By W. W. DEBERARD

Associate Editor Engineering News-Record

FOR THE first time in ten years Dr. Karl Imhoff, German consulting sanitary engineer and inventor of the two-story type of sewage tank bearing his name, has visited the United States. It was the writer's privilege to accompany him and Langdon Pearse, sanitary engineer, Sanitary District of Chicago, on a tour of inspection of the large Calumet sewage-treatment works where two-story tanks are used. I was anxious to learn of the doctor's reaction on seeing this plant, which is equipped with all of the essential labor and modern high-grade machinery for ideal operation. A gasoline locomotive was pushing into the sludge beds a train of a dozen side-dump sludge cars and half a dozen men cut lawn on the area saved for future use.

Ten years ago engineers by the score were visiting Germany asking all manner of questions, begging blueprints and eager for operating data because sewage-treatment plants of the biological type in the United States at that time were few and operation data scarce. For ten years Germany has built few sewage-works. "We are too poor," said the doctor. "Only those absolutely essential are even operated and it is surprising how few sewage plants are absolutely necessary. The tables are now turned. Within two weeks I have seen many works not in existence ten years ago. America now has taken the lead. The only activated-sludge plant in Germany is a unit at my laboratory."

At Calumet—Dr. Imhoff's first observation was of the incoming sewage. "The morning's grist," said Mr. Pearse, "rather fresh and well comminuted," the sewage having been through the centrifugal pumps and coarse screens. "It carries a lot of paper," I remarked. "Yes, American sewages always have much more paper than German sewages," said the doctor. Then we came to the chimney-like gas vents at the base of which was a thick heavy black scum, perhaps a foot or more thick. "Good," said the doctor. "But you must clean out the channels and add the scum to the sludge-drying beds." He could not understand a scum on the tanks which though not large in quantity was being skimmed off and dumped into the gas vents. The scum was greenish from algae and oily from garage discharges. "It is not solid material from the sewage," explained Mr. Mohlman, chief chemist for the Sanitary District, much to Dr. Imhoff's relief, for at first he thought that by some means the gas traps were not operating and sludge was being carried to the surface. He advised against putting this oily algal growth into the gas vents, for the whole must eventually be removed. This was just one indication of the little economies for which his eye had been trained in recent years to look.

Then we came to a tank with the sludge discharging by means of air lift, an inky black heavy liquid having the consistency of curdled milk and an odor not unlike fresh humus. "Good, proper and ripe," ejaculated the doctor. Farther along he hopped into a bed of dried sludge and brought out for inspection a cake 4 in. thick of dark brown porous cork-like humus with little or no odor which he proclaimed ideal. The bed had the characteristic irregular cracking after drying on the sand for two weeks.

"What causes the higher level of scum here, Doctor?" asked Mr. Pearse, as we came to gas vents nearly full of black foam. "Tanks which went into operation in the fall have given no trouble while those that were started in the winter have only settled down to regular work after considerable foaming."

"Acid methane formation in the winter," was the answer, "which did not permit the tanks to ripen all winter long. Then an accumulation of the wrong kind of organism persisted. The solution is to draw off the sludge frequently, probably twice a month."

Conditions in Germany—Dr. Imhoff indicated that many plants have been closed down there. Only the Ruhrverbund plants which discharge into the Ruhr River have to produce a high-grade effluent, for this is one of the few rivers used for water supply. The trend of present German practice is toward economy, both in operation and design. In extending the usefulness of existing plants, the period of settling has been shortened and existing sludge capacity increased by separate sludge-digestion tanks into which the fresh sludge, mixed with well-ripened sludge, is pumped. This has proved a practical way of taking care of the sludge, the mixture with well-ripened sludge giving inoffensive digestion. This practice is somewhat analogous to the practice of John D. Watson of Birmingham, England, who uses well-ripened sludge to seed the fresh sludge from septic tanks, in order to promote quick, inoffensive digestion.

The effect of heat upon the digestion of sludge is important. Probably the sludge chamber of the Imhoff tank is at a more uniform temperature the year around than in most tanks of other types and certainly more so than in the sludge-digestion experiments made in the United States, where the sludge is pumped into a separate basin and allowed to stand indefinitely and chill. Experiments are being conducted at Essen upon the effect of heat, both on Imhoff tanks and on separate sludge digestion, the heat being supplied by introducing small amounts of hot water every day through the sludge outlet pipe. A certain amount of liquor is likewise removed to even up displacement. The hot water is supplied by burning the gases from the gas slot under a small hot water boiler. Dr. Imhoff believes that the digestion of sludge should be more uniform and faster in a warmer climate where the sludge can be kept at summer temperatures the year around. (California and Texas engineers please note.)

"We are very poor," reiterated the doctor. "We must economize all we can. Some of our sewers are concrete-lined open trenches and recently in hunting for the cheapest kind of treatment we have found shallow sedimentation will give us a fair result compared with deep basins. In fact six basins not deeper than sludge beds have been built at one point. The area as well as depth is now taken into account in the latest design of the Imhoff tanks, whereas formerly we paid more attention to depth. We use less 'flowing through' depth and add as much depth as we can afford to the sludge-digestion chamber."

It is evident that necessary economy may force some interesting developments in German sewage-works. One last remark of Dr. Imhoff impressed itself on me in these days of the elevation of the so-called business man to administrative engineering positions: Although Germany has had a revolution the technical men in charge of technical works operation are not disturbed.

For the Contractor and the Engineer

Poured Construction Joints for Concrete Pavements

BY J. G. BRAGG

Senior Testing Engineer, N. J. State Highway Commission

ENGINEERS who favor the installation of expansion joints at frequent intervals in concrete roads may abandon their theory in favor of smoother riding qualities, knowing from experience the difficulties encountered in obtaining a "smooth-riding" joint. There has been considerable doubt also as to the effectiveness of the conventional type of pre-molded joint, and core drill operations have proven that few of these joints are set according to plans and specifications. They are thrown out of alignment or raised off the subgrade by removal of the bulkhead and frequently do not

the paper bulkhead. The paper for each joint is, of course, discarded but the same metal top caps are used repeatedly. The accompanying photograph shows the McGovern poured joint as it is being installed on a section of a New Jersey state highway. The main advantages claimed for this type of joint are:

Smooth-riding quality, uniform thickness of joint and complete separation of slabs, exclusion of surface water from joints, greater capacity for expansion of slabs, and less and more efficient maintenance.

Economizing Materials Storage Space in Building Construction

BY HENRY S. HINES

W. G. Wilkins Co., Engineers and Architects, Pittsburgh, Pa.

STORAGE and handling of materials in building construction is always a problem in metropolitan districts, where traffic is so great streets are not usable for storage. Methods used in the construction of the Atlantic Bldg., a 24-story structure recently completed at the corner of Broad and Spruce Sts., Philadelphia, are believed to represent about the best practice in materials handling.

The building occupies the lot from Spruce to Manning St. and Broad St. to a restricted areaway at the rear of the building line and the absence of any material stored on the streets has been very noticeable. The sidewalk along Spruce St. was removed and at the completion of excavation was planked over. Trap doors were cut in the planking, allowing the trucks to back up to the curb and dump all foundation concrete material directly into bins at basement floor level, from there it was handled into portable mixers set at convenient places in the sub-basement.

The steel frame was erected by using two 80-ft. boom derricks, placed in such positions so as to reach three sides of the building. All material was "picked off" the wagons and trucks and landed on the floors. Delivery was timed according to the speed of erection. After the first floor steel was set and riveted this floor was planked over solid and a driveway provided through the rear of the building from Spruce to Manning St. and down the center corridor from the Broad St. entrance. Under this driveway was placed the cinder and sand bins, mixer, etc., for the fireproofing.

A 3-yd. bucket was placed in one of the elevator hatches and the cat head raised as each floor was poured. The elevator contractor followed the steel erection very closely with his main rails and the general contractor utilized these for his three material hoists, doing away with any street obstructions whatsoever.

The delivery of outside terra cotta, brick backing, window frames, etc., was made directly onto these hoists and distributed on their respective floors. A portable mixer was placed in the sub-basement near one hoist and all mortar was lifted in wheelbarrows and distributed directly where wanted.

There is a 31-in. monolithic concrete top floor over

JOINT FORM ALSO SERVES AS BULKHEAD

therefore insure a complete separation of adjacent slabs. A serious defect also of the pre-molded joint is the lack of bond between the slabs and joint material, expansion and contraction of the slabs permitting a separation or crevice in the joint through which surface water may reach the subgrade.

A new type of poured joint is being used to some extent on New Jersey pavements, and the results obtained to date are quite commendable. While poured joints are generally frowned upon because the cost of installation is considered to be prohibitive, the type under discussion has many features tending toward economy of operation, bringing it in close competition with the pre-molded joint. Briefly, the method consists of installing a corrugated paper bulkhead which is left in place without forming an obstruction to the strikeboards or finishing belts. This paper bulkhead is later removed, leaving a clean-cut opening of whatever joint width is desired, and this opening is then filled with a 40-60 mixture of pre-mixed asphalt and sand. During the process of pouring and finishing the concrete, a sheet-metal cap is placed on the top edge of

the entire building. For this work the aggregates were stored at a convenient place on the first floor, a portable mixer was placed near one of the hoists in such way that it would dump directly into a concrete buggy which remained on the hoist, then hoisted and delivered to the floor where wanted. These hoists were used by the night crew to lift the tile, conduit and all other material for the next day's run.

The elevator contractor used a gasoline hoist in one hatch for his equipment. The plumbing and heating contractor rigged an electric hoist in one of the air shafts which took care of all their material. There were three Skinner engines weighing 10 tons each unloaded on the first floor and lowered to sub-basement through one of the elevator hatches. All the plastering material was handled through the basement.

At times it taxed our limited storage space inside the building but we were able to keep everything entirely off the street and due to this fact the police and highway departments have given us every consideration.

Joseph F. Kuntz of Pittsburgh, Pa., was the architect. The writer represented both architect and owner on the job. Metzger, Fisher & White of Philadelphia were the general contractors with A. Erickson, superintendent.

A Self Reading Traffic Chart

BY JACOB L. CRANE, JR.

Municipal Development Engineer, Chicago

FOR the purpose of expediting the registration of traffic counts at busy intersections a graphical chart is used. The advantage of the one shown lies in the

A SIMPLIFIED TRAFFIC COUNTING CHART

fact that the recorder jots down each vehicle showing graphically its origin and its direction of travel to and from the intersection. The chart gives the flow of traffic in both directions on all four streets and also the direction of the flow around the corners.

One recorder has taken a record on this chart of traffic running up to 1,000 machines an hour and two men can take a record of the busiest intersection en-

From Job and Office

Hints that Cut Cost and Time

countered. To secure the same information on ordinary traffic counts charts would ordinarily require from four to sixteen men.

In the view herewith the count is an actual one taken at Lake Bluff, Ill., Green Bay and Scranton Sts. between 7 and 8 a.m., June 16, 1923.

Spreading the Gospel of Traffic Safety

IN A recent county safety parade, the Wayne County (Michigan) Road Commissioners took advantage of the occasion to spread the gospel of traffic safety. The float herewith pictured shows the means used.

Box-Car Loader Made From Parts Obtained From Scrap Pile

A PIECE of equipment which has given efficient service was recently made by W. R. Hoback, engineer for the Gager Lime & Manufacturing Co., Sherwood, Tenn., entirely from parts obtained from the scrap pile excepting for the motor which drives it. It is a conveyor box-car loader used mainly for loading lime into box cars.

The machine is mounted on three casters, which makes it easy to move in any direction and in and out of the cars. The frame, which is of timber is 18 ft. long. On its under side, about 6 ft. from the lower end,

CONVEYOR LOADER MADE FROM SCRAP MATERIAL

From Job and Office

For Contractor and Engineer

is mounted a 1½-in. shaft fitted with a 14-in. steel pulley having a face of 3 in. This is belt-driven direct from the motor's 4-in. pulley. The opposite end of the shaft is fitted with a 6-in. sprocket which is chain-connected to the head pulley at the upper end of the frame. Directly under the driving shaft is a steel support, made up of ¼ x 3-in. flat bars. This takes care of the greater part of the loader's weight and also serves as a support for a pair of return idlers.

The belt was also taken from the scrap pile. It is 12 in. wide, lagged with 16-gage sheet iron turned up 4 in. at the sides, which prevents spillage and increases the carrying capacity.

The motor is of 2-hp. capacity. Current is supplied through one cable, of which there is sufficient surplus to permit moving the machine about. It will load 30 to 40 tons per hour. The machine is also adjustable as to height and lowering for different-sized cars.

Movie Machine to Make Continuous Construction Record

IN ORDER to obtain a practically continuous record of construction operations on a large western job a motor-operated moving picture machine was mounted in a small house at a point commanding a good view of the work. The mechanism was arranged for automatic operation except that the current was shut off at night.

HOUSING FOR AUTOMATIC MOVIE CAMERA

Construction is designed to avoid excessive heat that might effect the film. Wires supply current for timing and cranking motors.

Two small motors were employed, one for operating a "contactor" or timing device, by which the second motor, which cranks the camera, was started and stopped. The contactor was designed to be adjusted for various speeds permitting a range from 2 min. to 2 hr. in the time between exposures. When the contactor mechanism closed the contact the cranking motor turned the camera crank 90 deg. which caused the camera to make two exposures or frames. The purpose in this plan was to provide a film, which when projected at the normal rate of 16 exposures a second, would show rapidly the sequence of operations throughout the entire construction period.

Steam Shovel Moves Steel Storage Tank

A GASOLINE filling station recently erected in the Middle West offered quite a problem to the contractor. The station was to be equipped with a 15,000-gal. steel storage tank, but since the station was about one quarter mile from the nearest railroad spur, the contractor was confronted with the necessity of finding some means of moving the tank that would be both cheap and quick. The size of the tank prohibited ordinary hauling as it weighed more than 5½ tons, and was about 25 ft. long and 9 ft. in diameter. Finally a nearby steam shovel was secured for the job. The dipper and dipper handle were removed and a chain cradle was placed around the tank and made fast to the sheave block. The shovel then easily lifted the tank clear of the ground and with a man walking at either end of the tank to prevent undue swinging, it was carried across a field about a quarter of a mile, and placed in a 12-ft. excavation. The continuous treads on the shovel made movement across lots possible with a considerable saving in time.

Sewer Outlet Through Concrete Dock

BY D. H. FLEMING

City Engineer, Owen Sound, Ontario

THE CITY of Owen Sound was recently confronted with the necessity of providing an outlet through the concrete deck of a government dock for a 36-in. concrete pipe sewer line. The substructure of the dock afforded no support for the concrete pipe, and the concrete deck presented construction obstacles. Decision was then made to remove sections from rear and front concrete blocks supporting the decking, and insert a steel flume, 3 ft. square.

Blocks were removed by drilling five or six holes almost half way through the concrete and in an almost horizontal plane. Drilling was done on the front face of the dock with a steam jack hammer operated from a raft; and the holes were kept clean by a ½-in. hose line from a city water tap. Holes were spaced so that they controlled an area 3x6 ft. in plan. They were then loaded with dynamite and shot, one or two holes

SECTION OF DOCK SHOWS FLUME INSTALLED

at a time, by an experienced man. In this way the block was shot clean and was easily removed. The steel flume was then inserted, forms were set and the other half of each block was repoured.

The flume was made of $\frac{1}{2}$ -in. steel sheets with 3-in. angles $\frac{1}{2}$ in. thick at the corners.

Device Measures Height of Concrete Cores

BY G. W. HUTCHINSON

Assistant Engineer, North Carolina Highway Commission

THE testing of concrete cores drilled from finished pavements makes it necessary to have a suitable method by which the height of the specimen can be measured and proper correction ("Correction Data for Comparative Test Results from Field Specimens" *Proceedings*, American Concrete Institute, 1923) made for comparison of the test result secured with those obtained from specimens of standard size. Numerous

THREE-POINT DEVICE FOR MEASURING CORES

methods, including measurements by displacement and calipers, have been tried out by the Division of Tests and Investigations of the North Carolina Highway Commission, but the most satisfactory one consists of a three-point device shown in the accompanying photograph.

The use of this device allows consideration to be given to the irregularities of the top and bottom of the specimen when obtaining the average height. The core rests horizontally on two circular supports held by a pair of guide rods and which are adjustable according to the height of the core. At both ends of the device are the frames holding three screws which are brought in contact with the ends of the core for taking actual measurements. The frames are movable but can be held at convenient positions on the guide rods by means of thumb-set screws.

The core is placed on the supports and one frame brought into position to touch the end of the core. It

From Job and Office Hints that Cut Cost and Time

is then clamped and held in that position. The other frame is moved into place with respect to the other end of the core and then clamped and its position marked by means of a sliding lug on one of the guides. The three screws in each frame are then manipulated until they just touch the ends of the core. When the core is to be removed, to allow the measurements to be taken, the second mentioned frame is unclamped and moved back and the core taken out. The frame is then moved forward into its original position in contact with the lug on the guide rod. The distance between the three opposite sets of screw points is then measured and the average of the three readings taken as the height of the core.

The average measurements of repeated operations check very closely when this method is used. The three points measured are equidistant from the center and outside of the core and also from each other.

How Jacksonville Saved Money on Manhole-Cover Replacements

BY C. V. IMESON

Engineer of Sewers, Jacksonville, Florida

AN IMPROVED manhole cover designed to eliminate costly replacements of worn-out manhole covers in paved streets, brought out by the Sewer Department, Jacksonville, Florida, and adopted as standard, is shown in the accompanying drawing. A careful check of replacement costs has shown an average cost of approximately \$50 for each job, which cost includes repairs to the street. The adoption of the cover shown here-with brings the cost down to about \$6, with no repairs to the street necessary.

Barricading the street while repairs are made has been eliminated. About one and one-half hours' time of one man is all that is necessary to break out the old ring, insert the new one and place the filler back of the ring.

MANHOLE COVER OF INEXPENSIVE DESIGN

From Job and Office

For Contractor and Engineer

Derrick and Gin-Pole Lift Heavy Girder

IN PLACING a 68-ton plate girder 55 ft. long and 11½ ft. high at the fifth floor level of the Straus Building, Chicago, the load was divided equally between one of the two regular erection derricks and a special gin pole, each having a 100-hp. hoist. The guyed derrick which handled one end of the girder has a 123-ft. mast and 110-ft. boom, both of box lattice construction. The gin pole was a 50-ft. stick of Norway pine 20x20 in., guyed

ERECTING A 68-TON PLATE GIRDER

by six 1½-in. lines and having a set of blocks and tackle by which it could be boomed up in the same way as the derrick. The upper six-sheave hoisting block was slung from cable wrapping around the head of the pole.

Metal and Concrete Ties in India

Steel, cast-iron and concrete ties are used extensively on railways in India, besides various native and imported wood ties. The Northwestern Ry. is reported to have laid 1,200 miles of line with cast-iron plate ties in the past few years, while in 1922-1923 it laid about a hundred miles with the Stent concrete tie described in *Engineering News-Record*, Sept. 27, page 511. Steel trough ties are said to be in good condition after thirty years' service. It is thought they may be introduced again, although none have been purchased by this road for about twenty years. On the Great Indian Peninsula Ry., wood ties have been largely replaced with cast-iron pot ties. Both plate and pot ties consist of two separate cast-iron rail supports connected by a steel tie bar, and the Stent tie is an adaptation of the plate type in concrete construction.

Steady Output of 400 Cu.Yd. Per Day with a high mark of 600 cu.yd. has been attained in pouring concrete on the sewage disposal plant at Jones Island, Milwaukee, through efficient use and placement of concreting plant. All concrete is handled from a central plant and is chuted either from the hoist tower or a rehoist tower to all parts of the work, the ground plan of the structure being 650 x 750 ft., with the highest point of concrete averaging 20 ft. The central mixing plant includes two tilting mixers, two steel hoist towers, 216 ft. high with 1½ yd. capacity buckets. The towers are so arranged that power is supplied both hoists by a 100-hp. double-drum electric hoist. Aggregate is fed into the mixers from two overhead bins, each about 100-yd. capacity, these being fed by two 100-yd. per hour capacity bucket chain elevators. The entire bin feeding apparatus is electrically driven. A cement bin of about two-car capacity is located close to the bins, but is used for emergency storage only, a gravity trolley system of cement containers of the bottom-dump type, each of about 80 bags capacity, being constantly used to dispatch cement to the mixers direct from cement cars. The two main towers at the mixing plant supply one line of chutes 450 ft. long to a rehoist tower 196 ft. high. This rehoist tower in turn supplies a 120-ft. tower in the center of the job, which supports a line of chutes 280 ft. long on each side of the tower with a 50-ft. counterweight chute on each end, which is used to pour the circular tanks in the center of the job. A guy derrick of 10-ton capacity with a 115-ft. mast and 100-ft. boom supports the double counterweight chute system with total operating radius of 170 ft. This is placed in four different working setups and supplies concrete either direct from the two main hoist towers or from the rehoist tower. The mixers are operated alternately, and with specifications calling for 1½ min. mix have reached the maximum of 600 cu.yd. per day in a continuous pouring. The information herein was supplied by the T. L. Smith Co.

To show in a few minutes the progress of work occupying several months, a series of moving pictures is being taken during the erection of the 32-story steel frame Straus Building at Chicago. In Grant Park, at a point opposite the new building, a wooden tower was built, with camera house having a tripod cemented to the floor and supporting the camera. Every morning, the photographer mounts the tower and runs a few feet of film. When the building is completed these strips will be run as a continuous picture.

Sinking a Shaft Through Rock will often uncover seams from which there is a considerable flow of water, causing discomfort to the workmen and poor results when placing the concrete lining. A method of taking care of this water was used in a rock shaft in New York City and is briefly outlined as follows: At the place in the rock where there is a considerable flow of water, two or three holes are drilled, in the same horizontal plane, a little below the outlet of the water. Into these holes are inserted square iron rods of sufficient length to project to within several inches of the form (when it is placed). These rods are then covered with sheet metal and the space between the rock and the sheet metal plugged with oakum, dipped in grout. A brick dam, about 5 in. wide and at least 6 in. high, is built in the approximate form of a segment of a circle, and a 1-in. pipe placed flush with the sheet metal and the inside face of the dam. The other end of this pipe is threaded and the pipe should be long enough to project well beyond the future inside surface of the concrete shaft lining. An elbow and a length of pipe can be screwed on this end and the pipe wedged with pieces of rock at the other end to reduce the strain on the pipe through the dam. This pipe will take care of the water during the drilling. After the shaft lining concrete has been poured, grout is forced into the pipe leading from the dam, and when sufficient time has elapsed this pipe is cut off flush with the shaft lining, the dam remaining embedded in the concrete. It was found that no leaks occurred in any of the shafts where this method was employed.—*Contractors Atlas*.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

In Defense of the Cement Supply Man

Sir—I read with great interest the letter of O. T. Reece, County Engineer, Neosho County, Kansas, in your issue of Oct. 4, 1923.

The profits of the building supply merchant are the subject of much speculation, agitation and misinformation. The impression Mr. Reece seeks to convey in regard to the distributor's profit on cement is too good to be true. The "tribute of twenty-five cents to sixty cents per barrel" needs explanation from Mr. Reece—explanation backed up by a detailed recital of circumstances surrounding it.

From a first hand knowledge of portland cement manufacturing and distribution, I question the accuracy of Mr. Reece's statement regarding the size of the tribute unless it was at a period when through the blundering shortsightedness of highway officials, road construction was delayed for cement, and stocks, bought at a premium, were diverted to save the same highway officials' faces.

Mr. Reece, like many others, is able to see only one side of the shield, unable to see that the economic distribution of any commodity cannot be planned and carried out on the basis of an individual operation. Mr. Reece can be assured of one thing. If it was not for the entire distribution system furnished by the construction material merchant, not only his county, but every farmer, builder and contractor in his county, would pay a good deal more for cement than they are at present doing.

The supply merchant offers to Mr. Reece and all county and state officials every facility for economic and even distribution of cement regularly throughout the year. That this offer is not taken advantage of is the reason for the roar that occasionally goes up from public officials.

The supply merchants of Neosho County, Kansas, are citizens and tax-payers, and Mr. Reece is the servant of citizens and tax-payers, so it is his duty to work with all, for the good of all; and while I do not personally know a single supply merchant in the locality presided over by Mr. Reece, yet I am sure they are just as willing to honestly and legitimately aid the county in its efforts to secure materials at a fair price as is Mr. Reece. E. K. CORMACK,

Detroit, Mich., Business Counselor,
Oct. 9, 1923. National Builders Supply Association.

Decomposed Rock Under New York City

Sir—In your issue of Sept. 27, 1923, an article discussing the rock foundation at the Public Library on 42nd St. raises some questions of the future decomposition of the bed rock in New York. There is an implied suggestion that since the surface rock at the site of the library shows some decomposition, such decomposition may be generally expected elsewhere in the town, with a resulting danger to foundations which may be based upon rock, now sound, that may in the future become weakened through surface decay.

Decay of the surface rock of the Manhattan schist series has been observed at a number of places on Manhattan Island and in Westchester County. In the excavations for the old subway in the 42nd St. neighborhood weak material near the surface was exposed in several places and removed in the process of excavation; the excavation of shaft 17 of the Catskill aqueduct, at 6th Ave. in Bryant Park, exposed disintegrated rock near the surface. Because of deep decay the Catskill aqueduct tunnel was located in some places 700 ft. below the surface.

It is undoubtedly true, however, in spite of such local occurrences, that the New York rock as a whole has been

little affected by weathering since glacial time. The glacial markings on the rock surface so commonly observed on outcrops of the Manhattan series are the best evidence of the permanence and enduring character of the rock.

We are not even sure that the disintegration observed did not occur in pre-glacial time; it may be (and probably is) old rotten rock of pre-glacial origin not eroded by the continental ice advance. At the north approach of the Garrison tunnel of the Catskill aqueduct, near Garrison, N. Y., the excavation passed through about 600 ft. of rotten gneiss, undoubtedly a remnant of the original surface rock decayed in place, and not scraped away by the plowing action of the glacial ice. South of the glaciated boundary, the rock surface is covered by a mantle of disintegrated material, except where streams have removed it, but in the glaciated region such deposits are rare.

The New York rock is very old. There is no occasion to expect that it will change in the life of the structures based upon it. The city is fortunate in having as a foundation a rock which is as old and stable as can be found in any section of the country.

JAMES F. SANBORN,
New York City, Consulting Engineer.
Oct. 13, 1923.

Another Delay Caused by Red Tape

Sir—I have just read with very much interest your editorial in *Engineering News-Record*, of Oct. 4, 1923, p. 540, entitled, "Red Tape and a Pontoon Bridge." This brings to my mind a similar instance of a few weeks ago.

About the middle of September the Nueces and Frio Rivers, running through the boundaries of this county, were up about thirty feet due to heavy rains to the north and northwest of this county. At the present time there are no high-water structures on the highways crossing these streams and concrete slabs are used, since the water is very low normally and only loose gravel makes the slabs necessary. The high water carried out three crossings on the Frio and one on the Nueces, the last mentioned being about thirty-five miles northwest of Uvalde and on highway No. 4, an important mail and freight route to the counties northwest of here which are not served with a railroad.

Just as soon as possible the author made a trip to this crossing and decided that a temporary affair made of sand bags would be the most economical crossing that could be built in the shortest possible time. Immediately upon returning to Uvalde, communication was obtained with the chief engineer officer at Ft. Sam Houston, requesting 500 sand bags. The author was informed that although plenty of sand bags were available, permission for their use would have to be obtained from the Secretary of War. A wire was sent the Secretary of War on Sept. 24 requesting permission to use 500 sand bags from the engineer warehouse at Ft. Sam Houston. On Sept. 26 a wire was received to the effect that the order had been referred to Ft. Sam Houston. On Sept. 28 a wire was received from Ft. Sam Houston to the effect that rice bags could be obtained from a Houston, Texas, firm for 5c. each, cheaper than the sand bags used by the army (so the wire stated), and requested the county to obtain the bags from this firm.

The reader will please bear in mind that this last wire was received four days after the first wire sent to the Secretary of War. In the meantime, fearing that the delay was becoming expensive and irritating to the public, cement sacks in sufficient quantity, but costing 10c. each, were obtained and the temporary crossing was built and was ready for traffic by the time the wire of the 28th was received.

This in the opinion of the author is just another case of where the army could have been of great assistance to a community with practically no expense and very little trouble. Just before this incident occurred, the author spent the greater part of two days assisting an army convoy, consisting of four heavy cars and five trucks, in finding a crossing over the Nueces River in order that they might reach Marfa, Texas, in time for maneuvers at that place. It is supposed that if this incident had not taken place, no answer at all to telegrams would have been received.

Uvalde, Texas, M. B. HODGES, County Engineer,
Oct. 9, 1923. Uvalde County, Texas.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

President Coolidge is Taking Up with the State Department, it is understood, the matter of calling an international conference to discuss oil pollution. It was stated at the White House that the President attaches much importance to this matter. It is expected that he will request active consideration of the entire subject in the hope that remedies may be attempted at the earliest possible moment.

The Governor of Hawaii Is En Route to Washington to take up with Federal authorities and members of Congress the matter of extending the Federal aid plan to the highways of that island. Porto Rico has similar plans. Apparently highway officials of the various states have no objection to such extensions of the act since their organization recently has admitted to membership the highway commissions of those islands.

For the Purpose of Drafting a uniform building code for all future building construction in the national parks, the superintendents of the national parks of the United States will meet at Yellowstone Park the week beginning Oct. 22. By request of Secretary Work of the Interior Department to Secretary of Commerce Hoover, J. M. Gries, chief of the Building and Housing Division of the Department of Commerce, will attend the meeting.

A Proposed National Forestry Policy has been formulated by a special committee of the Chamber of Commerce of the United States (Washington, D. C.) and is being sent out for ballot to the 1,200 business organizations making up the membership of the Chamber. Among the eight items to be voted on are proposals for federal and municipal acquisition and planting of waste lands; for a national forest council; for a national survey and inventory of forest resources; for increased federal appropriations for the protection of timber lands against fire; and for an enlargement of federal forest research work.

A Committee on Russian Trade has been formed with Henry T. Hunt, former member of the Railroad Labor board, as chairman, and with headquarters at 120 Broadway, New York City. The committee will prepare an industrial report, investigations for which are being made by experts, including Valerian E. Greaves, a former professor of law in the University of Petrograd, and Ellery A. Baker, formerly in charge of the industrial department of the National City Bank, and will co-operate with export bodies and trade associations of American manufacturers to obtain credit insurance on shipments and to make arrangements for financing trade with Russia to make use of the extensive resources of the Russian Soviet Republic.

C. & N.W. Celebrates 75th Year

The 75th anniversary of the Chicago & Northwestern Ry. was observed Oct. 24 by ceremonies including a dinner to men who have been in the company's service for fifty years or more. From the first 10-mile line between Chicago and Maywood the system has grown to a total of some 10,000 miles extending into nine states.

Washouts on Government Railway in Alaska

A severe rainstorm combined with a high tide 6 ft. above any record level has put 100 miles of The Alaska R.R. out of commission, according to a telegraphic communication received by Secretary of the Interior Hubert Work from railroad officials at Anchorage, Alaska.

No estimate of the damage is furnished, but the entire section of the line between Seward and Potter has suffered from washed-out embankments and cave-ins on cuts. Two large bridges near Spencer Glacier and Bartlett Glacier have been washed away. The bridge destroyed at Spencer Glacier is a 120-ft. span.

Information is not full at this time, but it is believed the line can be reopened within two weeks, was the report from Alaska.

British Claim Damages on Rio Grande Reclamation Project

The American and British Claims Arbitration, an international tribunal, will hold a hearing in London on Nov. 5 to consider claims growing out of the construction of the Rio Grande reclamation project in Texas and Mexico by the Reclamation Bureau of the Interior Department.

The claims, ranging from \$3,000,000 to \$5,000,000, represent alleged damages suffered by British capitalists, who attempted to develop irrigation along the Rio Grande River in Texas and Mexico some years before the American government took up the project. Later, after its construction by the United States, the British capitalists charged that the Reclamation Service of the United States was responsible for their failure and had wrongfully deprived them of their rights.

The State Department represents the United States in denying the equity of the claims and at the hearing will present written briefs and arguments against granting them. Sir William Willcocks, a British irrigation engineer, is expected to give oral testimony in behalf of the British subjects.

Arthur P. Davis, recently dismissed, by Secretary of Interior Work as Director of the Reclamation Service, has sailed at the request of Secretary of State Hughes to aid in presenting the case of the United States.

Am. Soc. C. E. Fall Meeting in Virginia

Main Meeting at Richmond With Boat Trip to Hampton Roads and Washington

Engineering News-Record Staff Report

Excellent attendance and increased interest in the technical sessions marked the fall meeting of the American Society of Civil Engineers which was held Oct. 17-20 between Richmond, Va., the Hampton Roads district, and Washington, D. C. Just before the end of the meeting it was announced that 471 had registered, which included a greater proportion of non-residents as usual, and nearly 200 took the two-day boat ride which included stops at William and Mary College, at various places in the Hampton Roads district, and ended in Washington, where trips were made to the Arlington experimental farm of the Bureau of Public Roads and around the city of Washington. Entertainment included a Southern buffet dinner, entertainment and dance in Richmond, automobile trips around the city of Richmond, and a luncheon by the Washington Section on the final day.

No business was transacted, except the unanimous and enthusiastic endorsement of the letter which the Board of Direction had prepared to send to Dr. Hubert Work, Secretary of the Interior, in answer to his earlier letter explaining or attempting to explain his action in dismissing Arthur P. Davis from the Reclamation Service. This letter is printed in another column. Announcement was also made of the award of prizes noted in this journal last week.

TECHNICAL SESSIONS

The technical sessions comprised two morning general meetings, the first devoted to highways and the second to the port problems of Hampton Roads, and a simultaneous afternoon session of, in one room, the power division, and, in another room, the highway division. All were very well attended, and while there was not time for much voluntary discussion there had been arranged a more than usual amount of discussion which illuminated the general subjects treated.

The main paper in the road session was entitled "Fundamental Principles of Highway Financing," by Thomas H. MacDonald, chief of the Bureau of Public Roads. Mr. MacDonald prefaced his remarks by stating that it is time that people be made to understand that the engineer is to be trusted in matters of finance, particularly in financial policies for such matters as road building. In this, he explained, engineers were much more sound than the banker. He said a financial policy for road building must be based on the earning capacity of the highways and requires an examination in each locality before a policy is outlined. This examination should discover the saving in the cost of maintenance and operation of the vehicle, the earnings due to increased value of prop-

erty served, the earnings due to the time saved, all of which means that the benefits to society, to industry including agriculture, and to the road users must be analyzed. The extent of the improvements planned as necessary should not be in excess of an earning capacity. He said that there has been in no state a successful pay-as-you-go policy, and that there must be authority for taxes to support the bonds which ought to go only for permanent improvements, the motor tax to go for maintenance alone.

HIGHWAY SESSIONS

George E. Hamlin, superintendent of repairs of the State Highway Commission of Connecticut, and J. S. Mackay, chief, Division of Highway Economics and Transport of the Bureau of Public Roads, both discussed, under the head "Road Service in Industrial Regions," the results of the well-known Connecticut traffic survey which is just completing its first year. They repeated the figures regarding the first three months of this survey, which have already been published, and indicated that much valuable material is to come from the whole year's survey. Mr. Hamlin, in addition, called attention to some of the necessities for a road service in an industrial region. He noted the fact that there must be markers to speed up traffic and that the numbering system of roads must be elaborated. He called attention to the fact that the whole New England States system had agreed now on a single system of numbering so that the tourist could follow a road through all of the states. He emphasized the necessity for policing roads. A certain amount of traffic increase can be expected by such methods, but, after all, in the East roads are rapidly becoming saturated and the only solution is to widen or parallel. We must expect new trunk lines for fast and safe traffic. Continuity of service is demanded, and as a part of this snow removal is a necessity in the North. One tractor with a plow can open 10 miles of highway in Connecticut; 1,500 miles of highway were kept open for \$175,000 last year—\$120 per mile under very extreme conditions.

Prof. Mackay emphasized the necessity for traffic surveys and called attention to the Connecticut, the California, and the Tennessee work, and stated that Pennsylvania is to start this month on one of the most elaborate surveys ever undertaken. He said that the field for motor transportation in the future is (1) urban motor truck transportation in congested areas; (2) organization of motor freight service to supplement and extend the present service of rail and waterway; (3) short-haul zone of freight under 30 miles, non-competitive service; (4) transportation of a limited number of small commodities, where delivery time and cost of goods are important factors. He does not believe that there is any danger of competition with the more established freight services, but that special fields are bound to develop.

In the highway division special sectional meeting, C. M. Upham, chief engineer of the North Carolina State Highway Commission, described the new development of the system in his state, and the work was commented on by Clifford Older, of the Illinois Highway Department, and George H. Biles, formerly commissioner of highways of

Illinois Central R.R. to Start Electrification in Chicago

The Illinois Central R. R. Co. has applied to the Interstate Commerce Commission for permission to issue preferred stock not to exceed \$12,022,450 par value and \$12,022,450 of common stock. The latter is to be issued from time to time at the request of the holders of preferred stock and to be exchanged share for share for that stock.

The funds thus secured are to be applied upon the electrification of the company's lines within the city of Chicago.

In its statement to the Interstate Commerce Commission, the Illinois Central estimates that the work ultimately will cost \$88,801,562. Eighteen years will be required to complete the work, it is estimated.

Prof. Wagner New President of Rose Polytechnic Institute

Frank K. Wagner, for twenty-eight years a professor of engineering at Rose Polytechnic Institute at Terre Haute, Ind., and acting president since the resignation of Dr. Philip B. Woodward last May, has been elected president of the school. Professor Wagner graduated from the University of Michigan in 1883 with an A. M. degree and also the degree of mechanical engineer. He was an instructor in the engineering school at the University of Michigan at two different periods, between which he was sent to Mexico by the Thompson-Houston Electric Co. of Lynn, Mass., for whom he did engineering construction in Mexico City and built a street lighting plant in Pueblo.

The school was recently moved from within the city of Terre Haute to a new building and extensive grounds in the open country near the city (see *Engineering News-Record*, Aug. 30, p. 351.)

Pennsylvania. In the power division, W. S. Lee, chief engineer of the Southern Power Co. and the Quebec Development Co., outlined the developments of the Southern Appalachian power system. He called attention to the fact that in the southern district super-power was already in operation, but that it was of a different type than in any other part of the country. Here they have no large blocks of power and they do not send the power long distances, but the various companies are tied together over an extended area and the interconnection consists in the repeated transfer of power from one to the next adjoining district. In effect, this constitutes the transfer of power over the whole area. He also showed motion pictures of the construction of several of the large power plants in the South.

Thursday morning's session was devoted to a categorical description of the port problem of the Hampton Roads district and to the showing of some motion pictures by A. T. Goldbeck, of the Bureau of Public Roads, on the operation of the road testing work at the Arlington farms, outside of Washington.

In addition to the foregoing meetings, there was an informal conference of representatives of the local section held one afternoon.

Am. Soc. C. E. Convention Condemns Dr. Work

Protest Sent Secretary for Summary Removal of A. P. Davis and Implied Slander of Engineers

After a detailed investigation of the action of Secretary of Interior Work in dismissing A. P. Davis from the position of Director of the Reclamation Service, the American Society of Civil Engineers, in an open session at the fall meeting of the society at Richmond last week adopted the recommendation of the Board of Direction that a condemnatory letter of Dr. Work's action be dispatched him immediately. The letter offers a vigorous protest of the Secretary's action and his slanderous implication that engineers are not possessed of the highest business qualifications. The letter, which was sent Dr. Work Oct. 17, follows:

"Your courteous reply of Aug. 14 to our inquiry of June 27 has been very carefully considered, and the whole matter of your dismissal of Director A. P. Davis of the Reclamation Service has been investigated by this Board, aided by a special committee of two fair-minded engineers, widely experienced in public service and business affairs, one of whom is an honorary member and the other a past-president of this society.

"We regret to have to state that after mature deliberation we feel constrained to protest against your action with the utmost vigor.

"1—Because the dismissal, made so suddenly and but little over three months after you became secretary, was arbitrary, and was unjust to a highly efficient and experienced public official, a most eminent civil engineer, of long recognized national and international standing in his profession, whose high qualifications you yourself have certified by offering to make him consulting engineer of the Reclamation Service.

"2—Because the action necessarily must undermine the morale and loyalty of the whole Reclamation Service, tending to substitute political standing for merit, and leading to the danger that the public funds may be wasted through inefficiency. Similar action applied to other technical bureaus would demoralize the entire technical and scientific service of the government.

"3—Because the action was taken by the device of nominally abolishing the position and immediately creating its equivalent under another name, a subterfuge which, as we are informed, it has been attempted to legalize by an ex-post facto executive order. Furthermore, the charge repeatedly has been made in the press, and without denial by you, that your offer to retain Mr. Davis as consulting engineer of the Reclamation Service was on condition that he omit to state that his resignation was requested by you. Of this fact your letter contained no reference.

EFFECT OF WORK'S ACTION

"4—Because there is great danger that the effect of your action eventually may lead to the waste of vast sums of public funds to meet political demands put forward on behalf of selfish private interests. Disagreeing entirely with your views, we consider it established that efficient technical bureaus, such as the Reclamation Service in the past

(with its world-wide recognition as a model for other nations) can meet all the just needs of the government irrigation projects. Farmers generally throughout the United States are suffering under present conditions no less than those on reclamation projects.

"Engineering ability and experience are essential to the direction of the management no less than to the building of the reclamation projects.

"5—Because business and engineering ability both are necessary qualifications for the efficient discharge of the duties of the Director of the Reclamation Service, or, as now called, the Commissioner of Reclamation.

"Indeed, the whole engineering profession resents most strongly the slander (implied in your letter) that engineers cannot, or at least do not possess business qualifications of the highest order. In transportation, in mining, mechanical, electrical and other great industries, engineering executives play a most important part. Engineers are presidents of the Pennsylvania R.R., the New Haven, the Delaware & Hudson, the Chicago & Northwestern, the Santa Fe, the Great Northern, the Chicago & Great Western, and many others. Both presidents of our two big electrical companies are engineers; many of our large industrial and manufacturing operators are headed by engineers; in fact, engineers play important parts in business affairs in the long list of human activities in the United States. The fact that hundreds of thousands of Americans are content to trust investments of billions of dollars to the hands of engineers is ample proof—if any be needed—of the falsity of the charge that engineers are not business men.

"Your explanation, therefore, is inadequate in every respect. Your action is of a character most dangerous as well as unjust. We protest it in the strongest terms.

"The Board of Direction of the American Society of Civil Engineers.

"By C. F. LOWETH,
President,
"JOHN H. DUNLAP,
Secretary."

More Power to Be Developed at Stave Lake, B. C.

Work has been started recently by the British Columbia Electric Company on a plant to develop more power at Stave Lake on the properties acquired from the Western Canada Power Co. A total of 157,000 hp., it is estimated, may be added to the present output and it is intended that this shall be developed in three separate units as the market may require.

The first development will be a 25,000 hp. addition to the present Stave Falls plant and will be located in a separate structure to be erected near by and operated by the same crew as the present plant aided with remote control apparatus. The second plant will be located on the upper end of Stave Lake and will be supplied with water from Alouette Lakes by the aid of a dam on that lake and a 3,900-ft. tunnel. This plant will utilize a drop of about 140 ft. and will develop 12,000 hp. The third plant will have a capacity of 120,000 hp. and will be located about 3½ miles down the river from the present power house.

Illinois Nears 1,000 Miles Record of Hard Roads in Year

Illinois' goal of 1,000 mi. of hard road before the close of 1923 seems within reach. The State Division of Highways announced on Oct. 15 that 906.42 mi. had been completed and that with favorable weather for the next five or six weeks the thousand-mile mark should be reached. During the week ending Oct. 11 a new week's record was set with 51.21 mi. The report shows there are now 118 mixers, 9,600 men and 2,200 teams employed in building new roads for Illinois. Last year Illinois set a record of 722 mi. of hard roads.

To Form Joint Committee on Structural Safety

In order to carry on the work inaugurated by its committee on structural safety, the New York Section of the American Society of Civil Engineers at a meeting held on Oct. 17, to which it had invited representatives of the architects and builders, resolved to ask the local architectural societies to co-operate with it in the formation of a joint committee to consider the whole subject and make recommendations to their respective societies. The adoption of this resolution followed an animated discussion of the report of the section's committee on structural safety in which the fact was brought out that, although there is some divergence of views as to the architect's or engineer's responsibility for the execution of his design, the architects and engineers agree that until there has been a radical change in the present methods of building which will result in none but competent builders being allowed to undertake any work, laws or changes in building codes will be of little value. Both sides feel that it is necessary that they should co-operate to arouse public opinion to the necessity of putting a stop to construction by irresponsible builders.

For Reference—New York Subway Articles Reprinted

Realizing the importance, for reference purposes, of a complete description of all engineering features of New York City's rapid transit system, *Engineering News*, in 1914, engaged Fred Lavis, consulting engineer, with a long experience in railroad and general construction work, to prepare a series of articles on this subject. These articles were published beginning Oct. 1, 1914, and in response to numerous requests they were reprinted in book form. A recent examination of our stock-room showed that 150 copies of this book are still available for distribution, and while the supply lasts they will be sent to any *Engineering News-Record* reader on receipt of 25c. to cover postage and handling charges.

The book consists of 73 pp. (9x12 in. in size) profusely illustrated with photographs and drawings. The text covers such subjects as history and extent of rapid transit in New York, organization of engineering staff, construction arrangements and operating contracts, superstructure and track, ventilation, drainage and waterproofing, subsurface structures, timbering, excavation, underpinning, tunnels and concrete work. The final chapter is on elevated railways.

A.A.E. Board of Directors Re-elects Drayer

Resolution Also Adopted Protesting Against Dismissal of Davis by Work

At the quarterly meeting of the board of directors of the American Association of Engineers, Oct. 4, 5 and 6, C. E. Drayer was unanimously re-elected secretary and H. W. Clausen re-elected as treasurer.

Other action of the board follows:

The conventions committee's report on San Francisco as the next place of meeting was accepted. The date is not set but will be after June 10, 1924. A resolution of protest on the dismissal of A. P. Davis as director of the U. S. Reclamation Service was directed to the Secretary of the Interior. The annual publicity contest by chapters will be held under the same rules as in the past. It starts Nov. 1 and ends May 15. Felicitations were extended by resolution to the President of Mexico on recognition of his country and a formal resolution will be directed to the engineers of Japan expressing the feelings of American engineers on the recent earthquake disaster. Owing to the appointment of Dr. F. H. Newell as consulting engineer of the Pennsylvania Giant Power Survey he has had to be released as field secretary.

DAVIS RESOLUTION

The Davis resolution reads as follows:

"Whereas, Arthur P. Davis, Director of the U. S. Reclamation Service, was recently removed from the office that is believed he has filled honorably and efficiently; and

"Whereas, the U. S. Reclamation Service investigates the feasibility and practicability of engineering works, and engages in the design, construction and maintenance of such works; and

"Whereas, under the direction of technically trained heads the service has for a long time been free from all suggestion of political interference, improper conduct, or inefficiency; and

"Whereas, it should be evident that all engineering and technical divisions of the Government should be free from political interference, and that engineers or technically trained men should be able to administer them with peculiar effectiveness;

"Be it resolved by the Board of Directors of the American Association of Engineers in regular meeting assembled that it strongly deprecates the replacement of an able and faithful engineer by a politician under the plea that a "business man" can serve more effectively than an engineer as head of the Reclamation Service; that it deplores the woeful ignorance of facts indicated when it is implied that an engineer is incapable of exercising business judgment equal or superior to that possessed by the follower of any other profession or calling; that it vigorously protests against the injection of politics into the affairs of one of our Government's most important technical divisions; that it requests and urges that the next Congress institute a rigid public investigation of the removal of an engineer and the appointment of a non-technical man to head the U. S. Reclamation Service; and that copies of this resolution be sent to the Secretary of the Interior of the United States and furnished to the press."

Work Addresses Reclamation Fact-Finding Body

Starts Committee on Investigation of U. S. Reclamation Service After Substituting Bureau

The following statement was made by Secretary of the Interior Work Oct. 15, at Washington, D. C., at the opening meeting of the Fact-Finding Committee to investigate government reclamation methods:

"Soon after I was called upon to act as Secretary of the Interior, in March, 1923, my attention was particularly directed to conditions relating to the reclamation projects constructed or being constructed by the department in the western states, among which I have lived for thirty-five years.

"Through complaints from organizations of water users, individual water users, reports of agents, inspectors, official records of the department and Congress, it appeared that nearly all of the projects were in such condition that some radical reforms or improvements must be had if they were to be saved, farmers protected from loss of their homes, and the return of the money advanced by the government for their construction and maintenance was to be secured.

COMPLAINTS AND CRITICISM

"The complaints and criticisms cover a variety of points, too numerous to be described here, but included charges that in many of the projects the original estimates under which settlers were induced to go upon the projects were from 50 to 100 per cent too low, and that the actual cost has been so great that it is impossible for the farmers to pay out within the time and manner fixed by law, or even at all; that mistakes, engineering and otherwise, had been made which added materially to the cost of constructed projects; that others had been undertaken that should never have been started; that the overhead costs of the service and many of the individual projects, all borne by water users, were burdensome and excessive.

"Under the system used in the Reclamation Service I have been unable to get figures that appear to be dependable as to the cost of individual projects or the total money expended on all projects. It is represented, taken from the records of the bureau, that the government's total investment to June 30, 1923, in round numbers is \$181,000,000, and its total receipts about \$46,000,000, leaving a balance invested and unpaid of \$135,000,000.

"The Reclamation Service, for which this department is responsible, apparently requires reorganization. Annual reports on some projects indicate their insolvency and pending failure. Out of the 28 projects only one has met its obligations as they fell due. Long extensions of time for payments due are being urged individually and by projects. The original twenty-year period for payment is expiring on certain projects and an additional twenty-year extension is being asked. In one instance, such extension is to be preceded by a five-year moratorium.

"Reclamation of arid lands by irrigation from government funds, as heretofore practiced, is failing on a majority of projects as a business procedure and

Portland Lets Pipe-Line Contract for \$2,571,403

A contract for the laying of Bull Run water-supply line, conduit No. 3, has been awarded by Portland, Oregon, to the Willamette Iron & Steel Works of that city, at \$2,571,403 for lock-bar steel pipe. The total length of this line is 132,000 ft. of which 52,400 ft. will be 58 in. and 80,000 ft. 50 in. in diameter. Under arrangements made by the successful bidder with the East Jersey Pipe Co. the plates will be shipped from Leetsdale, Pa., in a partially fabricated condition and the Willamette company will complete the operations of rolling, pressing, testing and dipping at their Portland plant. It is expected that this arrangement will be conducive to the placing of additional lock-bar pipe on the Pacific Coast. The Portland contract is the result of alternative bids asked on either lock-bar or riveted steel pipe. Other bids were as follows:

	Lock-Bar	Riveted
J. H. Tillman Co.,	\$3,032,135	\$2,628,645
F. J. Shea,		2,647,161
T. A. Gillespie Co.,	2,696,090	
Western Pipe & Steel Works, of California,		2,708,381
Lyon S. Atkinson, Jr., Los Angeles,		3,093,367

Fred M. Randlett is chief engineer of the Portland Water Bureau.

New Quebec Power Project Begun

The Laurentian Hydro-Electric, Ltd., has completed its financial arrangements and begun construction work for the development of power on the North River, Quebec. It has a franchise for ten years to supply light and power to the towns of St. Jerome, St. Adele, Strawbridge, Val Morin and other places in the Laurentian district. William Kennedy, Jr., and E. W. Loignon are retained as engineers and will supervise the construction of the plant.

must be promptly readjusted as to methods of reimbursement for funds appropriated and for the purpose of securing to the settler a permanent home.

"Your committee is requested to survey the whole subject in its entirety, and give to the bureau your opinions concerning our operating methods that we may avoid errors, and finally your recommendations which Congress may study and which should ultimately preserve the sanctity of contract, secure to farmers safety for their investments already made and insure a return of invested funds. I want to improve and extend the service in every way possible, and solicit your suggestions and recommendations.

"Government reclamation has accomplished much. There is a great field for its future. Reclamation in the West by private enterprise was begun thirty years before the government began this work and has largely redeemed the West. Government reclamation should make a comparable showing, relieved as it is, from interest charges, which is the basis of calculation in all enterprises employing private capital. I am anxious that a policy may be developed that will safeguard the future of government reclamation which is my only concern in this inquiry."

Cement Manufacturers Protective Association Ordered Dissolved

By an order handed down on Oct. 23 the Cement Manufacturers' Protective Association, a trade organization comprising 19 of the largest cement makers of the Lehigh and Hudson River districts, was ordered dissolved by Federal Judge Knox, New York City. Thus disposition is made of the equity case against the defendant organization, a case filed at the same time in 1921 when criminal indictments were returned against many of the association's members and officials of the member companies.

The criminal trial was held last year but ended in a jury disagreement. At that time it was agreed that all of the evidence adduced during the criminal proceedings should be the basis of any action in the equity case.

The Cement Manufacturers' Protective Association has not been functioning, except superficially, for a year.

War Camp Suits Must Give Bill of Particulars

In an opinion handed down by Federal Judge John E. Sater in the case of the government against the A. Bentley & Sons Co. of Toledo, Ohio, the builders of Camp Sherman, Judge Sater upheld the motion of the defendant that the government submit a bill of particulars as to the fraud with which the contractor is charged. Judge Sater ruled that the defendant company is entitled to such reasonable particulars as will indicate upon what evidence is to be given, namely, as to what materials or what quantity of the same were wasted, as to wherein the defendant purchased and resold at a profit materials and equipment needed and not needed.

The court also ruled that as the petition charged fraud, it should show with reasonable certainty of what the fraud consists, how it escaped detection by the government officer in charge, and why it was not detected at the time of its perpetration or for so long a time thereafter; that the petition should show that the plaintiff did not consent or was ignorant of the subletting of portions of the work to various subcontractors. The judge also ruled that the averment about the patriotism of the persons and concerns entrusted with the performance of emergency work should be omitted, as there is nothing in the contract which indicates that patriotism was any part of the consideration.

In regard to the government's claim that the contractor is operating on a cost-plus contract was in the position of a trustee of the government Judge Sater stated that the claim is not sustained in law, that when the government enters into a contract with an individual or corporation it divests itself of its sovereign character as to that particular transaction and takes that of an ordinary citizen and submits to the same law as governs individuals under like circumstances. He upheld the claim of the government that under the contract it had a right to make a deliberate review of the payments made the contractor in order to correct mistakes which arose due to the urgency of making prompt payment, but he stipulated that if the government has, as it claims, found that the contractor defrauded it of \$5,000,000 the defendant contractor is entitled to particulars.

Engineering Societies

Calendar

Annual Meetings

AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS, St. Petersburg, Fla.; Annual Convention, Atlanta, Ga., Nov. 12-16.

CITY MANAGERS' ASSOCIATION, Lawrence, Kansas; Annual Meeting, Washington, D. C., Nov. 13-15.

AMERICAN ROADBUILDERS' ASSOCIATION, New York City; Annual Convention, Chicago, Jan. 11-18.

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York City; Annual Meeting, New York, Jan. 16, 17.

AMERICAN CONCRETE INSTITUTE, Detroit, Mich. Annual meeting (20th anniversary), Chicago, Ill., Feb. 25-28, 1924.

The Brooklyn Engineers' Club on Nov. 8 will have for special feature a paper, with lantern slides, "Arching Effect in Soil," by Emil Bie, engineer of the New York Board of Estimate.

The North Carolina Section of the American Water Works Association will meet in New Bern, N. C., Nov. 13-15, and discuss papers on metering, fire protection, algae in water supplies, stream-flow records, filter operation and direct-oxidation.

The Four-States Section, American Water Works Association, had a luncheon at the Engineers Club, Philadelphia, preceding the conference on water pollution held at the same place on Oct. 16, and reported elsewhere in this issue. About 70 members were present. George W. Fuller, president of the association, called attention to new constitutional provisions under which there will be nine geographical sections instead of the present six, thus making feasible the creation of a Canadian section, whereas heretofore the Canadian provinces have been included with several American states in a section. To avoid confusion the term "division" instead of "section" will be applied to the Chemical and Bacteriological Section and any other technical sections that may hereafter be formed.

Personal Notes

F. C. MACGRUDER has accepted a position as city engineer of Enid, Okla., which city plans to spend a million dollars next year in construction work for an additional water supply.

ADAMS & ADAMS, consulting engineers, Detroit, is the new firm name of William H. Adams and his brother, Ralph W. Adams, whose recent admission to partnership with him is announced. The offices of the firm are in the Campau Bldg., Detroit, and they will practice in general construction engineering.

KENNETH M. CAMERON, assistant chief engineer of the Department of Public Works of Canada since 1918, has been appointed chief engineer of

that department succeeding the late Arthur St. Laurent. Mr. Cameron is a graduate of and has a master's degree in hydraulics from McGill University. He had early railroad experience in the office of the chief engineer of the Canadian Pacific Ry., was inspection engineer of the Canadian Niagara Power Co., for some time was with Smith, Kerry and Chace, consulting engineers of Toronto, and in the Public Works Department was located successively at London, Sherbrooke, and at Ottawa in the dredging branch.

DANIEL C. COOPER, formerly construction superintendent with the United States Gypsum Co., at its Oakfield, N. Y., and Lancaster, Ohio, plants, is now connected with the Power Corp. of New York, Watertown, N. Y., as construction engineer.

EARL PHILLIPS, city engineer of Peru, Ind., has resigned and the appointment of PAUL SHADINGER to fill out the unexpired term is announced.

JOHN E. ALLEN, formerly with William Steele & Sons, of Philadelphia, as concrete engineer, is now engineer in the structural division of Stone & Webster, Inc., Boston, Mass.

A. D. MCARTY, Urbana, Ill., has been appointed secretary of the Illinois Municipal League, and will give all his time to this work. He succeeds Prof. R. M. Story, who has resigned.

E. C. LAWTON, who has been made a highway research specialist in the Bureau of Public Roads, Washington, D. C., formerly was assistant engineer of construction on main highway work at Buffalo, N. Y., for the New York State Commission of Highways.

G. W. FLEMING, formerly assistant structural engineer with the Leonard Construction Co., Chicago, Ill., is now doing similar work with the George F. Hart Engineering Corp. and is located in Brooklyn, N. Y.

M. F. LONGWILL, division engineer of the Detroit division of the Wabash R.R., with headquarters at Montpelier, Ohio, has been promoted to assistant chief engineer of the eastern district of the Wabash lines, with headquarters at St. Louis, Mo. Mr. Longwill is a graduate of Ohio Northern University. He has held various positions with the Missouri Pacific Ry. and the Union Ry. of Memphis, and has been with the Wabash lines since 1918.

GEORGE D. FAIRTACE, recently city engineer of Dallas, Texas, has been appointed city manager and engineer of Highland Park, Texas.

J. D. TRAMMEL, recently chief engineer of the Spavinaw water supply project at Tulsa, Okla., in which were constructed at a cost of \$6,800,000 a dam and a 61-mi. pipe line, has opened offices at Ft. Worth, Texas., in the Waggoner Bldg., and will conduct a consulting practice.

T. H. DILLON, of the firm of Titus & Dillon, engineers, and at present county engineer of Shelby County, Texas, has been appointed also engineer on the highway work of Panola County, Texas.

JOSEPH GRESHAM, formerly county engineer of Mason County, Texas, and S. A. DIETZ, formerly engineer for Hidalgo County, have been appointed assistant county engineers of Jim Wells County, Texas, under County Engineer L. W. S. MANTELL, at Alice, Texas.

Obituary

FREDERICK T. BAGSHAW, civil engineer, died recently in Winnipeg, where he had resided for many years. He was born in England where he received his education, and was engaged in railway construction there and in Australia before going to Canada, where he has been in charge of several civic undertakings and has superintended bridge and track construction for the Canadian Northern Ry.

WILLIAM G. BLIGH, for many years executive engineer of the Public Works Department of India but more recently a resident of Toronto, Canada, died Oct. 16 in Calgary, Alta., aged 77 years. Mr. Bligh designed and constructed some of the largest irrigation works in India and Burma, and his book, "Practical Design of Irrigation Works," is a recognized text book on the subject.

GENERAL EDMUND HAYES, engineer and formerly chief of the staff of engineers for the state of New York, died Oct. 19 at his home in Buffalo, N. Y., from a stroke of apoplexy at the age of 74 years. He was born in Farmington, Me., and attended Dartmouth College two years and graduated from the Massachusetts Institute of Technology. In 1874, becoming associated with General Field, at Buffalo, he entered the business of the Morrison & Field Bridge Co., later the Central Bridge Co., and was engaged in many projects during the period of railroad expansion of the 70's. After this firm sold to the United States Steel Corp., General Hayes became interested in the Ontario Power Co., the Fidelity Electric Power Co., and the Niagara, Lockport & Ontario Distribution Co., these interests later being sold to the government. It was as chief of staff of engineers of New York State that he won his commission.

HARRY H. HAMILTON, civil and chemical engineer, was killed Oct. 10, by falling into a vat of boiling chemicals at the St. Louis Coke and Chemical Works, where he was employed. Mr. Hamilton was 30 years old. He was a resident of Portland, Ore., and graduated in 1912 from the Oregon Agricultural College. He was an enlisted marine officer and saw service in France during the war.

COL. JAMES A. MCCREA, since 1920 vice-president of the Pennsylvania R.R. system in charge of the Central Region, died of pneumonia Oct. 17 in Allegheny, Pa., aged 48 years. Colonel McCrea, the son of the late James McCrea who was president of the Pennsylvania R.R. from 1907 to 1913, entered the service of this railroad in 1895, after graduation from Yale University, and rose rapidly from rodman to engineer of maintenance-of-way of the lines east, then was made superintendent of the Cincinnati Division and later was general manager of the Long Island lines. He served in France 1917 to 1919, first as general manager of transportation, then as a member of the general staff of the A. E. F., and was awarded a Distinguished Service Medal.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Export Ratios Need Study in Industrial Machinery Field

Virtual Withdrawal of German Goods Offers Opportunity to American Manufacturers

MANUFACTURERS of air compressors, according to statistics compiled by the Department of Commerce, have a better export business than manufacturers of concrete mixers. At first thought, according to an analysis of export ratios for various types of equipment by W. H. Rastall, chief of the department's industrial

the comparative business ability and sales effort manifested by the management of these different producers of machinery.

Conditions have now reached a point, according to the Department of Commerce, where American machinery manufacturers should give careful attention to their export business. Unusual opportunities are to be found in these foreign fields because Germany appears to be almost eliminated as a competitor. Before the war Germany furnished perhaps 45 per cent of the machinery that went into international trade and since the armistice there have

PRODUCTION AND EXPORTS OF CERTAIN CLASSES OF INDUSTRIAL MACHINERY IN 1921

machinery division, one might expect the advantage to lie with the concrete-mixer manufacturer because of the nature of the work and the surroundings under which his product is commonly employed.

Why, Mr. Rastall asks, should the percentage of export orders secured by a manufacturer of excavating machinery be twice as great as that of a manufacturer of machine tools? American excavating machinery usually represents a high state of engineering development. These units are frequently very costly and one might expect that the labor conditions in most foreign countries would make it unnecessary to employ machinery of this character, while machine tools are necessary for a great number of manufacturing operations and would seem to be in more general demand.

A great many similar questions naturally arise in considering the accompanying chart, which indicates the total volume of production and the percentage exported applying to certain classes of American industrial machinery, and it is interesting to speculate whether the situation illustrated by this diagram is the result of fundamental conditions or merely expresses

been times when the depreciated condition of the mark gave German manufacturers a peculiar advantage in this trade. That situation has now passed and in great measure German prices already exceed world-market levels. Experience shows that deliveries from German manufacturers are slow and frequently uncertain, and in a great many ways it is difficult for foreign buyers to buy in Germany on a basis that is at all satisfactory. Business that formerly went to Germany will more and more fall into other hands.

Although there are a number of countries in the world that produce machinery for export, the countries of most outstanding importance at present are Great Britain and the United States, and the indications are that the large volume of machinery business formerly secured by German manufacturers will now be awarded to either British or American producers.

QUALITY SHOULD BE BASIS

American engineering and American machinery are distinguished in the world's markets for their superiority. Americans are noted for their engineering achievements, but, because of this superiority, American machinery is

Rating Plates for Standard Concrete Mixers

Showing ratings and maximum capacities for standard sizes of concrete mixers, as adopted by the Joint Committee on Construction Equipment at Chicago, July 30, plates of which a sample is shown herewith, have been designed at the request of manufacturers for attachment to the machines to avoid any misrepresentation, over-rating or under-rating of mixers. It is announced by the Associated General Contractors that new plates will begin to

appear on equipment as soon as the different manufacturers can arrange their designs and shop practices to conform with the new standards. Complete standardization is to be achieved before January, 1925.

The sizes of paving and building mixers adopted as standard are as follows:

Paving Mixers	Building Mixers
21-B	21-S 5-S
13-E	28-S 7-S
7-E	14-S 31-S

Portland Cement Output

Monthly output records for the portland cement industry in the United States were broken during September when mills produced a total of 13,109,000 bbl. as compared with 11,424,000 bbl. in September of last year. Shipments for September, 1923, were 13,698,000 bbl., which is higher than for the same month a year ago, but less than for certain other months in 1922 and 1923. The foregoing figures are based on statistics issued by the Department of the Interior and prepared under the direction of Ernest F. Burdard, of the Geological Survey, from reports by portland cement producers.

For the first nine months of 1923 portland cement production totaled 101,016,000 bbl. as against 81,563,000 bbl. for the same period during 1922.

Shipments for the first nine months of 1923 totaled 104,607,000 bbl., a gain of 15,923,000 bbl. over the same period for 1922.

usually higher in price than similar equipment secured from foreign sources and must be marketed on a quality rather than a price basis. In other words, this trade, which formerly went to Germany, will now pass to British manufacturers unless American products are supported by constructive sales effort of such character as to demonstrate that American equipment is worth the price asked, and more. Manufacturers should now organize their sales effort along such lines as will accomplish this result.

Export business is becoming more and more essential to the prosperity of the individual manufacturer. The accompanying chart shows that it is vital for manufacturers of dredging and excavating machinery. The difference between a satisfactory or an unsatisfactory export ratio can easily represent the difference between profit and loss on the year's balance sheet. Manufacturers have a very definite opportunity to improve their export ratio, and it remains for them to make the sales effort necessary to secure these results. The present international situation provides an unusual opportunity.

Mixer Chokes on Contractor's 1: 2: 5 Charge

One of the Koehring Co.'s customers complained about the inability of the "Dandie" mixer to hold a 1:2:5 mix. A representative was sent out to investigate. He reported that the contractor was very much "peeced" and that the machine was certainly slopping. On investigation, however, he discovered that the contractor's conception of a 1:2:5 mix was one bag of cement, two wheelbarrows of sand and five wheelbarrows of stone. The contractor was complaining because the mixer wasn't big enough to take an extra wheelbarrow or two occasionally when the inspector was not looking.

Figures Show Scope of Brick, Tile and Terra Cotta Industry

The Department of Commerce announces that, according to reports made to it, the value of products of establishments engaged primarily in the manufacture of brick, tile, terra-cotta, fire-clay products, pottery, and non-clay refractories amounted to \$335,518,035 in 1922, as compared with \$278,492,385 in 1921, \$388,746,923 in 1920, and \$286,261,276 in 1919.

For brick, tile, terra-cotta, and fire-clay products the value reported for 1922 was \$229,435,610, which was an increase of 23 per cent over 1921 and 16.2 per cent over 1919, but a decrease of 14.1 per cent compared with 1920.

For the pottery industry the value of products in 1922 was \$91,986,297, which was an increase of 9.3 per cent over 1921 and 18.1 per cent over 1919, but a decrease of 13.8 per cent compared with 1920.

The reports for 1922 involve 1,973 establishments, including 1,651 primarily engaged in the manufacture of brick, tile, terra-cotta and fire-clay products, 270 primarily engaged in the manufacture of pottery, and 52 in the manufacture of non-clay refractories. Of the 1,973 establishments reporting in 1922, 331 were located in Ohio.

Prepared Roofing Simplified

At a meeting held in Washington, D. C., Sept. 26 at the Department of Commerce with representatives of the Division of Simplified Practice and the Chamber of Commerce of the United States, manufacturers, distributors and consumers of prepared roofing agreed to the following simplifications as being of benefit not only to the industry but also to the public at large:

1. To eliminate all grades or kinds of slate-surfaced and also stone-surfaced prepared roofing that do not measure up to the requirements of the "Class C Label" of the Underwriters Laboratories.

2. To reduce the varieties of smooth surface roofing to seven lines or grades—weights and qualities being considered.

This Simplified Practice Recommendation is to become effective Jan. 1, 1924, and is to hold for one year.

According to W. A. Durgin, chief of the Commerce Department's Division of Simplified Practice, this is another step in the general program fostered by Secretary Hoover for the elimination of waste in industry. "The proposed eliminations," he said, "were strongly supported by the American Institute of Architects, the National Retail Hardware Association representing 21,000 retail hardware dealers throughout the United States, the National Retail Lumber Dealers Association, the Southeastern Builders' Supply Association, and the Prepared Roofing Association."

Several other simplifications of building materials have been completed notably common and face clay brick. Others in process of completion are lumber, hollow building tile, cement brick, block and tile and clay drain tile. All of these simplifications are contributing to the general effort to reduce the needless wastes in the building field.

Business Notes

KOEHRING Co., Milwaukee, has let contracts for an addition of 100 ft. to its light erecting shop to increase its output of cranes, draglines and power shovels. Plans for another new shop site are now being drawn.

WESTINGHOUSE ELECTRIC & MANUFACTURING Co., at its South Philadelphia works, has established a general engineering division which will be devoted to the study of central station and industrial plant problems involving the application of steam power apparatus such as steam turbines, condensers and reduction gears. This department will also co-operate with the sales organization in providing engineering service to purchasers of this equipment.

REEVES BROTHERS Co., Alliance, Ohio, builders of steel tanks, oil refinery equipment, cement and mining machinery and crosscutting plants announces, effective Oct. 1, an office at 2012 L. C. Smith Building, Seattle, Wash., from which all Western business will be handled. Percy E. Wright, consulting mechanical engineer, has been appointed assistant sales manager of the company and will be in charge of the office.

Equipment and Materials

V-Shaped Snow Plow on Tractor Clears Full Width of Road

Designed for attachment to the front end of a Fordson tractor, a new model of V-shaped plow for clearing snow from the full width of highways at one operation has been designed by the Stark Plow Co., 943 Little Building,

Boston, Mass. It consists of a pair of 2-in. oak-plank wings, each 10 ft. 6 in. long, shod with road-grader steel blades and hinged to a nose casting at the front end, as shown in the accompanying photograph. Each oak wing or moldboard is flared at the top, the total height of the blade being 20 in. As the tractor travels at speeds of from 12 to 15 miles per hour, this flare-board is effective in catching the snow as it rises up on the moldboard and throwing it over toward the sides of the road.

The wings are adjustable, by means of a trip latch and pin, and may be set to clear any width of roadway from 8 to 16 ft. One of the advantages of the V-shaped plow, its manufacturers point out, is the elimination of side thrust, making possible the clearing of a wider strip at one operation and a higher traveling speed. The equipment is designed so that in a heavy storm a route may be covered quickly, clearing the whole width on the outward journey and repeating on the inbound trip before the snow becomes too deep to handle.

To the tractor chassis are bolted two U-shaped hoisting frames rigged with block and tackle for raising and lowering the plow. The rear end of the tractor is equipped with a platform for an operator. The weight of the plow attachment is 1,200 lb. While designed primarily for tractor operation, the plow can be adjusted for use on a motor truck. In practice it has been found that the best results are secured by equipping the tractor with weighted wheels with 10-in. solid rubber tires equipped with chains.

New Rust-Proofing for Wire

A new process termed "Galvannealing" for the application of a protective zinc coating to steel wire and wire fencing is being introduced by the Keystone Steel & Wire Co., Peoria, Ill., as an improvement upon ordinary galvanizing. The special advantage claimed is in permitting an extra heavy coat of zinc to be applied without fear of its flaking or peeling off. If such a heavy coating is applied by ordinary methods it is likely to separate from the steel when the wire is bent sharply, as in the weaving of fencing. In the new process, instead of employing pressure as usual to cause the zinc to adhere to

the steel, the coated wire is given a heat treatment by which the zinc becomes amalgamated with the surface of the steel so that it will not crack or flake off when the wire is bent or twisted. It is claimed that steel wire and woven fencing thus made have fully twice the life of ordinary galvanized material.

Light, Compact Concrete Mixer Is Hand Operated

Operated by hand and weighing only 400 lb., a concrete mixer with a capacity of 6 cu.ft., known as the "Shaker," has been developed and placed on the market by G. W. Adams, concrete contractor, San Antonio, Tex. The equipment is designed particularly for mixer jobs that have heretofore been done by the shovel and board method or where a large gang is not justified for operating a larger and more expensive power mixer. Simplicity is the keynote in the design of the hand-operated machine which has been made compact, light, and portable.

As shown in the accompanying illustration, the device consists of a steel drum pivoted on ball bearings to a steel frame carried on a two-wheeled carriage. The mixer is charged directly from wheelbarrows and is frequently mounted directly over the forms so that it may discharge into them. In operation, after the charge has been introduced, the drum is rotated by hand,

back and forth in a semicircle. Blades on the interior of the drum throw the material to and from the sides and through two grates located about 5 in. on either side of the axis of the drum. The manufacturer of this equipment states that about a dozen revolutions or "shakes" of the drum are sufficient to produce a satisfactory mixture. The charge is emptied by revolving the drum about its axis until its mouth points downward. It is claimed that with a gang of four or five men the output of the machine will range from 20 to 30 cu.yd. daily.

Crane Handles 98-Ton Girder

At a highway bridge crossing over the main line of the Boston & Albany R. R. at Beacon St., Boston, a 98-ton steel plate girder was received on flat cars, unloaded and raised to place between train schedules, the operation beginning at 10 p.m. and ending at 1:55 a.m. The work was done by the Phoenix Bridge Co., which employed a crane manufactured by the Industrial Works, Bay City, Mich., for handling the large girder. It is claimed that this is the largest girder ever handled by a single locomotive crane.

A Self-Adjusting Wrench

A self-adjusting wrench requiring no screwing up or down to make it "bite" or fit an object is being marketed by the Greater Service Co., Newark, N. J. By the use of a ratchet leverage system the teeth are inclined to each other, causing the grip to be stronger as the pull is increased. The wrench, which is known as the Robert, is equipped with a spring, as shown in the accompanying illustration, and its operation requires the use of only one hand.

The wrench is made of drop-forged carbon steel in only one size, a 12-in. length, which weighs 1½ lb. This size

will handle objects ranging from small nuts to 1½-in. pipe. The manufacturer is planning shortly to put on the market additional sizes, from 6 in. to 15 in.

Publications from the Construction Industry

Kerosene Engines—FULLER & JOHNSON MANUFACTURING CO., Madison, Wis., has published a 40-p. illustrated catalog on its throttling governor kerosene engines in sizes from 3 to 25 hp. The text deals with both stationary and portable units.

Hammer Drills—SULLIVAN MACHINERY CO., Chicago, has issued a 32-p. revised illustrated bulletin on its Rotator hammer drills. The new models described include the light-weight and auger patterns, as well as the standard drills with solid or hollow pistons and air and water-jet attachments. The drills are one-man hammer drills, weighing from 29 to 40 lb., designed to drill holes from 8 to 12 ft. deep for 1½-in. powder. They may be used as hand tools or on mountings.

Industrial Locomotives—BLOOMSBURG LOCOMOTIVE WORKS, Bloomsburg, Pa., has issued a 28-p. bulletin on its industrial locomotives of three types, a gasoline-engine-driven and two types of steam-engine-driven units. A feature of the gasoline locomotive is a mechanical speed control device working in connection with friction disk transmission. These units are built in sizes of 3, 4, and 6½ tons. The steam locomotives use oil fuel and the burners on the two models are of the vaporizing and the atomizing type. The oil-burning steam locomotives are particularly adapted to work where smoke and exhaust gases from internal combustion engines are objectionable, as in mines or tunnels.

Water for Swimming Pools—GRAVER CORP., East Chicago, Ind., in a 16-p. illustrated pamphlet presents data on its filtration equipment for supplying pure water to swimming pools. The equipment for recirculating, filtering and sterilizing the water permits the same supply to be used over and over again. Actual layouts of typical swimming pools are presented. The Graver filters are of the mechanical pressure type.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Fifty Big Contracts Since March Total \$157,460,646

Each week *Engineering News-Record* publishes a separate list of the large contracts awarded for the current issue. The accompanying table shows fifty large projects placed under contract during the period March 1 to Oct. 1, 1923. The list is composed of the largest awards taken from the various construction headings during these seven months and covers work in the United States and Canada.

This table gives the percentage of the various operations as follows: Buildings, 57%; Railroads, 9%; Streets and Roads, 4%; Waterworks, 3%; Sewers, 6%; Excavation and Dredging, 0.2%; Bridges, 2.7%; Dams, 5%; Power Plants, 13%.

The award for the railroad and telegraph system consisting of 330 mi. of track, a complete telegraph system and 660 mi. of fencing, amounting to \$12,000,000 was given to the firm of Peter-

son, Shirley & Gunther, Omaha, Neb. A 30-story telephone exchange building in New York was awarded to Marc Eidlitz & Son, Inc., of New York City, for the sum of \$11,250,000. The third largest contract is for the 16-story office and sales building at Chicago, Ill., and is being constructed by Wells Bros. Construction Co. of Chicago for \$8,000,000.

During this period the following number of contracts as reported in Construction News were awarded at the following prices (the amount quoted is the minimum taken as a base): 129 at \$10,000; 2,771 at \$25,000; 341 at \$50,000; 2,044 at \$100,000; 310 at \$200,000; 184 at \$500,000; 174 at \$1,000,000; 14 at \$5,000,000.

Business Briefs

Call money easy; rate 4@4½ per cent.

Time loans shows little variation during the last few weeks; 30, 60@90 day loans, to 6 months, 5@5½ per cent.

Painting costs for the \$868,529,000 worth of industrial and commercial building contracts noted in *Engineering News-Record* from Jan. 1 to Oct. 1 amount to \$20,000,000, of which \$8,000,000 is for paint materials. If one painter did all this work it would take him 2,740 years and he would receive \$12 per day during that time.

British steel output up. September ingot production, 695,100 tons, against 567,500 in August. Pig-iron output, 558,600 tons, compared with 599,800 during preceding month.

American steel output drops. September production of steel ingots, 3,159,283 tons, against 3,506,755 in August. Daily pig-iron output, 104,184 tons, compared with 111,274, during preceding month.

Duty free building materials allowed by Turkish Government, to construction companies granted concessions for reconstruction of cities destroyed in Western Asia Minor.

Storm and flood are the chief causes for the decline in crude oil output. Production for week of Oct. 13 was 2,125,350 bbl. against 2,157,400 bbl. of previous week.

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for in Construction News, pp. 227 to 238, are the following:

Capitol, Charleston, W. Va., \$2,500,000.

Water Plant, St. Louis, Mo., \$2,500,000.

Hospital, San Francisco, Calif., city and county, \$1,750,000.

Hotel, Louisville, Ky., Citizens Hotel Co., \$2,300,000.

Hotel, Memphis, Tenn., Southern Hotel Co., Inc., \$3,000,000.

Theatre and Office, Indianapolis, Ind., Monument Circle Realty Co., \$1,500,000.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction

News, pp. 227 to 238, are the following:

Hospital, Louisville, Ky., to Struck Construction Co., \$1,500,000.

Bank and Office, Los Angeles, Calif., to Scofield Eng. & Constr. Co., about \$1,250,000.

Hospital, New York, N. Y., to Nat. Constructors & Engineers, \$1,000,000.

Warehouse, Chicago, Ill., to J. Bheden & Co., \$1,000,000.

Factory, Jacksonville, Tenn., Du Pont Fibre Silk Co., \$4,000,000.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted.

Valuable suggestions on costs of work can be had by noting actual biddings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Oct. 4; the next, on Nov. 1.

Steel Products:	New York	Atlanta	Dallas	Chicago	Minneapolis	Denver	San Francisco	Seattle	Montreal

Explanation of Prices—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or — signs. For steel pipe, the prevailing discount from list price is given: 45-5% means a discount of 15 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b. Labor—Concrete laborers' rate, 93 $\frac{1}{2}$ c.; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. Tile price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu. yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5 $\frac{1}{2}$ x 8 x 11 $\frac{1}{2}$. Prices are all f.o.b. warehouses except C. I. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir, common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on pine lumber. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 95.58). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$47.43; 6-in., \$119.

Changes Since Last Week

While there has been a perceptible falling off in demand for iron, steel and textiles, activity continues in other materials with but little tendency toward an upward turn in prices.

Fabricated structural steel bookings fell off nearly 12 per cent and steel castings, 6 per cent, during September. Confidence in the trend of business, however, is evidenced by the recent heavy demand for railroad materials. The Baltimore and Ohio Railroad Co. has placed orders for 50,000 tons of steel rails to be delivered during 1924.

Including track fastenings, etc., the cost of this material will approximate \$4,300,000. This tonnage has been distributed as follows: Carnegie Steel Co., Pittsburgh, Pa., 25,000 tons; Illinois Steel Co., Gary, Ind., 4,000 tons; Cambria Steel Co., Johnstown, Pa., 10,000 tons; Inland Steel Co., Indiana Harbor, Ind., 3,000 tons; Bethlehem Steel Co., Steelton, Pa., 8,000 tons.

Building materials prices show little tendency to change. Of the nine cities reporting weekly to *Engineering News-Record*, but three show any revisions.

Dallas reports a decline of 62c. per 100 lb. in reinforcing bars and \$2 per ton in cast-iron pipe. An advance of \$3.50 per ton, however, is quoted in hydrated lime and 25c. per bbl. in common lump lime. A slight tendency to quote lower cement prices is prevalent in San Francisco and other points on the West Coast, due mostly to importations of foreign cement. Linseed oil rose 4c. per gal. in San Francisco during the week. Montreal shows a tendency toward higher rates for common labor; and firmness in black steel pipe.

Number 18

Light Ahead in Europe

WORLD politics, like a running stream, can be dammed to a certain height. Sooner or later the dam bursts or is overtopped. Last week the European muddle reached the overtopping stage. Whether or not there was more than mere coincidence in the timing of the Baldwin, Harvey and Smuts speeches and the Hughes-Curzon correspondence, it is quite evident that neither Great Britain nor the United States can stand idly by and see a foundation for future wars laid in a dismembered Germany and an international industrial compact between Lorraine iron and Ruhr coal. France is obsessed with her notions of current security and cannot be trusted to foresee the future. The less wounded nations must see ahead for her. If the proposed Hughes conference does nothing else it will at least make public the economic possibilities of the reparations settlement, which have hitherto been obscured by the cloud of international and domestic politics. The economic basis once established the path to agreement and means to insure it will be much easier.

A Unique Personality

CHARLES PROTEUS STEINMETZ was the greatest example in our generation of the triumph of mind over matter. No one who ever saw him will forget that gnome-like figure which had it been clothed in grotesque dress might have stepped out of fairy tale or ancient masque. But the mind was there behind this superficial covering and it carried its possessor to the heights. He was an inspiration to the theorist, because in his chosen line he was the supreme theorist in the world and yet so practical was his theory that for years he remained the technical mainstay of an intensely practical organization. Engineering lost a leader, industry one of its most ardent workers and social science one of its most devoted students when Steinmetz died.

Two Court Decisions

THE courts last week made initial decisions in two cases that have great interest to engineers and the construction industry. In Ohio Judge Sater, in one of the cantonment contract suits, made it clearly evident that the government must specify the exact losses it claims it suffered from the so-called wasteful camp construction during the war. Obscured as it is by the legal distinctions between the agency and the contract relations the camp contractors bore the government, the decision nevertheless indicates that the Department of Justice is to be forced to a more specific definition of the fraud it so vociferously has alleged against the engineers and contractors who helped win the war at the cantonment sites. The other case was the decision of Judge Knox in New York City that the Eastern open-price cement manufacturers association is a com-

bination in restraint of trade and therefore illegal. In view of the earlier decisions in the hardwood and tile case this one was to be expected. It is interesting to note, however, that Judge Knox is by no means convinced that the price and contract interchange methods under attack resulted in an exorbitant price of cement, and this, as we have pointed out before, is the question that engineers and contractors want most to have settled.

A Remarkable Runoff Record

NO BETTER example of the vagaries of rainfall and its consequent runoff could be found than the experience of Oklahoma City this summer. A river which had been dammed for water supply had a record flow up to May of this year of 11,000 sec.ft. In that month this was surpassed by 1,000 ft., not at all surprising considering the relatively short period over which the records of flow in this comparatively new country extend. But in the six months thereafter there were three successive floods, first 33,000 sec.ft., then 12,000 sec.ft. and now the last one, described in this issue, of 60,000 sec.ft. This is breaking records with a vengeance. Full data regarding the last remarkable runoff will be looked for by all interested in water storage and control.

Function of Contracting

SUBCONTRACTING perhaps receives its most complete modern expression in building construction. Years ago when railway construction was at its peak it might have claimed precedence as being most practiced in the multiplication of contracts. Then, on occasion, the subcontractor sublet parts of his contract and the sub-subcontractors relet their work to station men. Out of modern building practice has grown, as there once grew out of railway construction, a class of contractors who are more financiers and co-ordinators of construction operations than they are actual constructors. The reaction is a demand by some of the building trades that separate contracts be awarded them for the work for which ordinarily, now, they must seek subcontracts. A specific instance is the memorial to the Interdepartmental Board of Contracts and Adjustments urging separate contracts for the "mechanical elements," of federal buildings. Neither the claim nor the argument against it need concern us at this time. It will be noted merely that building construction practice furnishes a particularly clear illustration of a function of contracting that is commonly overlooked; this function is management of construction. In brief, contrary to common acceptance, the most important function of the general contractor is not to erect steel or brick or concrete, but to co-ordinate and synchronize construction operations and to assume responsibility for the owner. The contractor does not merely construct; he

furnishes a management and financing service and an insurance against risk. If we keep these truths clear, that if the contractor does not perform these functions there must be some other agency employed, we shall escape many of the false conclusions about cheapening construction by eliminating contractors' profits.

Why Not a Construction Show?

AN ENGINEERING and business congress of highway industries, which has true magnitude, has been developed around the annual meeting of the American Road Builders' Association. In Chicago in January each year the exhibition of road building materials and machines and the technical proceedings of the road builders' convention represent about the highest effort that has been attained in gathering together for business and education all the elements of a leading activity in the construction world. Because it is outstanding, indeed almost alone, as a construction exhibition, the road show draws visitors from all lines of the construction industry. The circumstance suggests the thought of the creation of a general construction-industries exhibition around which the associations of that industry can arrange their annual business and technical conventions. Is the idea practical? One sees no convincing reasons why it is not. Truly there are visible difficulties of exhibition space, hotel accommodations and convention scheduling, but they appear small when set against the time and money saved by exhibitors and visitors. The present road show is a nucleus to grow around. Contractors particularly would like to see it become, by extension of time, space and exhibits, a construction show. Indeed it is with this possibility in mind that this year the Associated General Contractors are entering partly into joint convention work with the American Road Builders Association. Why not a single annual construction show with a tributary business and technical congress of construction associations?

When to Use a Trestle

RECENT floods in the Middle West, notably those with which the Burlington Ry. has been afflicted, call attention again to the importance of the timber trestle in railway construction. An expedient of the early days of railroading, the trestle remains a necessary structure at many locations where economy is governing. But in the "cloudburst" country where a dry run may be converted once a year into a raging torrent the trestle is a dangerous element in operation. It may be questioned whether the use of the trestle has not been carried to extremes by perfunctory adoption of this type, with low cost as the primary consideration and with insufficient study of its suitability for such use. If in the engineer's judgment the trestle is the proper type of structure to be adopted he should give careful attention not only to substantial design of its superstructure but especially to its foundations and abutments. A guiding rule to be followed as far as conditions may permit or warrant in each particular case is contained in the following statement quoted from *Engineering News*, Sept. 29, 1910, p. 337: "Occasional washouts of trestles crossing small creeks or dry runs draw attention to trestle piling. Every year several failures of this class occur, and though not all produce train wrecks yet several of the worst wrecks of the last decade were due to such failures. It is fair to conclude that in planning structures in the territory

from the Missouri River to the Coast a dry run should always be regarded as a bank-full torrent. Since these ravines usually have a steep slope they offer the possibility of great scouring power, so that foundations of the most resistant type should be provided."

Protecting Trains From Washouts

THE failure of the Cole Creek trestle on the Burlington some weeks ago draws attention to the problem of the protection of trains in case of a washout. Automatic warning signals to indicate damage or destruction of trestles by fire and flood have been suggested and even tried experimentally. But the operation of such devices depends usually upon the movement or failure of some part of the structure. It is not unlikely that in many cases all parts may remain intact, though undermined, until the weight of a train causes collapse. Furthermore, the chances are against the reliability and observance of a signal or a series of signals at small structures where floods are infrequent and where the signal might remain unoperated for long periods. Automatic block signals with track circuits would afford little protection except in case of complete washout, since the track is usually the last part to fail. Inspection at low water may show a safe and stable structure, but when the water has risen and a torrent is flowing it is difficult to determine conditions of scour or undermining, while as a rule the bridges are too numerous and the storms too sudden to permit of thorough investigation at the critical time. With sudden storms the engineer may have no warning of conditions ahead of him. The structures may show him no sign of weakness and at night or in stormy weather he probably would not notice every small trestle. The problem, in fact, has not been satisfactorily solved.

Transverse Fissures in Steel Rails

NO MORE serious problem has ever confronted the rail manufacturers and users than that of preventing failures due to transverse fissures, a peculiarly dangerous type of failure because of the fact that it almost invariably occurs before the fissure reaches the surface of the rail. The transverse fissure as a specific type of rail failure was recognized twelve years ago during the investigation by the Interstate Commerce Commission of a serious railroad accident at Manchester, N. Y. Twelve years of study have not brought us much nearer determining the cause of this baffling type of failure. Instead, we are faced with an ever-increasing number of rail failures from this cause and a mass of contradictory evidence as to the cause.

But the rail users have been fortunate in one respect, for the man who first recognized the transverse fissure, the engineer-physicist of the Interstate Commerce Commission, has continued in that capacity and has persisted in the study which he started twelve years ago. From time to time during the past twelve years he has issued reports of his progress. The latest one, prepared some months ago, is abstracted elsewhere in this issue. In this report he brings forth more evidence to substantiate the theory which he has held for some years, as to the cause of transverse fissures, namely, that transverse fissures are caused and developed from their incipency by the cold rolling action of the car wheels.

Most of the evidence does indeed favor this theory, but in view of some of the contradictory evidence it is

difficult to accept it absolutely. A safer position would be to consider the cold rolling as the cause of the development of the fissures from their incipency, and the cause of the incipient fissure still undetermined. Two features of the evidence, brought out in this latest report more clearly than ever before, lead to this belief. The first is that certain heats are more subject to transverse fissures than others, and the second that rails rolled by certain mills in certain years are more subject to transverse fissures than rails rolled in other years or by other mills when laid in the same track. So convinced are some railroad officials that certain rollings or certain heats are superior to others that they remove all the rails of any heat from the track when the second failure occurs in that heat, and in some cases whole stretches of rail rolled in certain years have been removed from the track when still otherwise serviceable because of repeated failures by transverse fissures.

Another curious, though possibly unimportant, feature of the situation is the grouping of transverse fissures at certain geographical locations. Probably the increasing ability on the part of section foremen to recognize a transverse fissure and more knowledge of the conditions contributing to their development will eliminate this feature.

Undoubtedly the cold rolling of the rails under heavy axle loads used in this country has developed the transverse fissures from its incipency to ultimate failure, but as long as rails of the same section but of different manufacture or even different heats continue to give different results under the same traffic we are convinced that the cause will be found in some defect in the manufacture of the rail.

For a Federal Contract Law

AFTER some eighteen months' work, and the time taken has been no longer than the task required, a standard form of building and construction contract has been tentatively adopted by the Interdepartmental Board of Contracts and Adjustments. This contract is now before the construction industry for discussion and constructive criticism. Many changes both in fundamental practice and in technical details have already been suggested. Consideration of these changes need not occupy us. They will be adopted or disregarded as the board decides and a final contract form will be approved. This is the thing of substantial importance in all the work which has been done and is to come: a standard construction contract for federal public works is immediately ahead. There should follow a general federal contract law.

It is not possible here to consider the reasons, either political or technical, which stimulated present legislation governing federal contracts. Let us consider merely the number of laws which are the accumulation of years of legislation. In a compilation made by the board there are listed 224 separate statutes. Of these 40 apply to all government departments, 12 apply to two or more departments and 172 apply to only one department. Incidentally the proposed standard contract of necessity complies with all these laws. Herein has rested much of the difficulty in drafting it. It may be the reason why in making the final draft suggested revisions will not be made.

Law controls government contract procedure. It is important to hold this fact in mind. The government is

an abstract entity. It expresses itself concretely in contractual relations only by the statutes affecting contracts. It speaks and acts only through agents who can take no action that does not express the law. And the law is 224 separate statutes. All the forms of contracts of all the federal departments, which it is the purpose of the standard form to eliminate, are not a tithe as many. If a general contract form is needed, then, a general contract law is more needed.

Such a general act is contemplated by the board. In brief this act will repeal all conflicting and obsolete statutes and make uniform all provisions in one short law. If the board follows its procedure in drafting the standard contract form to invite aid in arriving at decisions from the whole construction industry, engineers and contractors can play a useful part in formulating the general federal contract law. There are few employers of which they have more loudly complained in the past. Let them be as ready to help put away the causes of complaint.

Arkansas Roads Redivivus

ARKANSAS has placed itself squarely in the roster of states having state highway systems and centralized direction of highway improvement. It is no longer the incorrigible member of the family of road building commonwealths. Uncle Sam can again let it share in federal aid which it alone of all 48 states has been denied during the year. Although the highway world will be a duller place lacking the southern state's fiery assaults on sundry and all who have ventured an intruding finger into its ways of managing its public roads, the change will be altogether good for Arkansas highway affairs.

Briefly a state highway law has been enacted. It creates a highway commission, establishes a system of state roads and provides a fund for constructing and maintaining these roads. Part of the funds raised will pay old road-district debts. No more road-improvement districts can be created and no more road-district bonds may be issued except under close restrictions. These provisions remove the cause of most of the highway tribulations which the state has suffered in the past. Motor vehicle owners will provide the money. There is a 4c. tax on gasoline, the highest gasoline tax in any state. Motor oil is taxed 10c., and license fees are virtually doubled. The new highway commission has true responsibility and real authority. Altogether Arkansas has a commendable road law. By its honest enforcement most of the past errors in highway management can be redeemed.

In recording this advance it is due Arkansas to remember that its errors in highway improvement have been faults of understanding rather than of enterprise. There are few states in the Union which have in the last five years shown a more determined spirit in lifting their highways out of the mud. The people have voted \$60,000,000 of bonds for road building and there are completed some 28,700 miles of improved road of which 3,871 miles are surfaced or paved roads. These are accomplishments which stand out even in comparison with the road building of the states of the North. Arkansas may well feel proud of its high enterprise in road building. That it has frequently been so greatly misdirected is a reason for regret. Uncontrolled local management of road improvement has no blacker page in its records.

Storage Dam at Cisco, Texas, Has Cutoff Wall Integral with Deck—Corrugated Footings Resist Sliding —Four-Mile Railway Constructed—Forms for Deck Used Thirty Times

E. M. URBAN
H. F. Friestedt Co., Contractors, Chicago, Ill.

BY FRANK W. CHAPPELL

This footing arrangement is clearly indicated by Fig. 1. As shown by Figs. 2 and 3, a cutoff wall of varying depth and thickness extends from end to end of the dam and into the abutting hills. It is reinforced throughout and doweled into the footings and the deck. Its greatest depth is 55 ft. below the natural ground.

No artificial roughening could be attempted on the thin limestone ledges. They were considered as being

as good merely as so much plain concrete of ordinary quality and only their weight was utilized. While the surface is somewhat wave-worn and fissured it is smooth in comparison to the areas involved. For safety it was taken as being perfectly smooth and the coefficient of friction as that for concrete on limestone. The deficiency was made up by inserting steel dowels at an angle of 45 deg., or practically parallel to the deck.

Buttresses resting on the thick mass of shale at El. 1,420 were anchored against sliding by simply

All concrete, except that in heavy retaining walls, is of a 1:2:4 mix; retaining walls are of 1:3:6 mix. Coarse aggregate consists of crushed local limestone, $\frac{1}{4}$ to $2\frac{1}{2}$ in. Fine aggregate is creek sand up to $\frac{1}{2}$ -in. particles. The first concrete poured was mixed with crusher screenings as sand. No means were provided for removing dust and 16 per cent of the screenings passed a 200-mesh sieve. The resulting mortar was high in strength, 1:3 briquettes showing 25 per cent higher tensile strength than the same mix of standard Ottawa sand. A great deal of trouble, however, was experienced with a heavy layer of laitance on each buttress lift. The fear that some of this chalky material might be left in the structure, together with the possibility of the dissolution of minute, uncoated particles under long submergence, led to the abandonment of screenings as sand.

Spillway Design.—The area of lands draining into the reservoir is 30 square miles. The country is rugged, sparsely settled and covered with growths of black jack oak and mesquite. The reservoir banks are generally precipitous and there is little cultivated land on the watershed. No records of stream flow have been kept and an attempt was made to collect testimony of persons living in the neighborhood, for determining flood flow. This was found to be conflicting and uncertain.

FIG. 2—BULKHEAD SECTION OF CISCO DAM

blasting out cavities under the footings. These were filled with concrete, poured monolithic with the footings.

Superstructure.—The buttress thicknesses are so proportioned that the greatest shearing stress in a horizontal plane will be 100 lb. per square inch. Some steel was inserted parallel to the deck to counterbalance defects in construction joints. Beams and slabs were designed for a compressive stress in concrete of 600 lb. per square inch, and steel in tension, 16,000 lb. per square inch. In proportioning and reinforcing the deck slab, all shear up to 50 lb. per square inch was assumed as being taken by concrete. Horizontal reinforcement is bent up to assume the excess of shearing stress above 50 lb. This design introduces into the lower reaches of the slab more horizontal steel than is required for tension, but this is unavoidable unless stirrups are used.

The deck is being poured in continuous sections of 72 ft., making each panel to extend over four buttress spans. Unusual care is being taken to make the slab watertight at expansion joints (Fig. 5). U-shaped strips of No. 11 copper, which have flanges cast into adjoining sections, allow of expansion without leakage. The slabs are separated by "elastite" strips placed against the face of the one first poured. Longitudinal construction joints are made with double keys and the surface of the previous day's work is cleaned and washed. Each section of deck is poured from top to bottom with the shortest possible intervals between the placing of successive batches. The engineers and the contractor considered the advisability of continuous pouring for each section of deck and concluded that the advantages were not sufficient to offset the uncertain quality of night work.

FIG. 3—SPILLWAY SECTION OF CISCO DAM

Calculations based on highwater marks designated by different individuals indicated a discharge varying from 8,000 to 15,000 sec.-ft.

In view of the excessive floods noted in various parts of Texas during the past, it was thought best to disregard all of the data collected on this particular stream as being incomplete and unreliable. Although it is extremely improbable that any intense tropical storm will ever break as far inland as Cisco, the total discharge capacity through and over the dam was made 36,000 sec.-ft., or 1,200 sec.-ft. per square mile.

Flood waters will be disposed of over a spillway 270 ft. long by 10 ft. deep and through two sluice gates. Since the greatest flood to be expected, excepting those great cloudbursts at intervals of fifty years or more, will be less than half the total discharge capacity, the spillway crest was designed for a 5-ft. depth of flow. The short duration of extraordinary stages makes it uneconomical and unnecessary to widen the crest to accommodate them. In addition the wide crest would form a broad-crested weir for low heads, with less discharge capacity than the sharper section and for local reasons it is desired to hold the fluctuations of water-level within

the lowest possible limits. The spillway apron will have a uniform thickness of 20 in. The discharge will be partly upon a limestone ledge and partly over the shale. In the latter case the apron is extended vertically for a distance of 10 ft. into the shale.

Two sluice gates, each having a clear opening 8 ft. square will be installed just north of the spillway. They will be electrically operated with remote control switches from the pump station or from the hilltop at the south end of the dam, at the pleasure of the operator. As above explained the sluice gates have been included in providing for the discharge of the creek. But in addition to this consideration, they are deemed necessary as emergency outlets.

Quantities and Cost.—The estimated quantities are: concrete 43,000 cu.yd.; steel, 1,000 tons; excavation, 95,000 cu.yd., and copper, 25,000 lb. A pumping station will be built within the dam, between buttresses 25 and 26, and a filtration plant will be built on the hillside below the dam. The total cost of the project will be approximately \$1,300,000.

The Elrod Engineering Co. of Dallas are consulting engineers for the city of Cisco, and prepared all plans for the dam and supervised its construction. The writer acted as chief designing engineer, and is responsible for the details. T. A. Hodges and J. G. Reagan have been resident engineers in charge of construction. The general contractor is the H. F. Friestedt Co. of Chicago.

Construction Plant and Methods

BY E. M. URBAN

Transportation was the primary problem in building the Cisco dam. The site was in an eroded and broken district four miles from the railway and there was no passable road to it. A railway was the first requirement, and it had to be built in a rough, rocky canyon following the meandering course of a small stream which it crossed three times on wooden bridges. This short railway was the sole means of transporting first the construction plant units and, then, all of the materials used in the construction of the dam. Over 1,000 tons of reinforcing steel, 600,000 ft. b.m. of lumber, 21,500

cu.yd. of sand, 43,000 cu.yd. of crushed stone and many carloads of miscellaneous supplies and materials were hauled over this road.

Plant Layout.—As the line of the railway was downstream to the dam it was necessary to locate the plant on the upstream side. A very simple and convenient arrangement, as shown by Fig. 6, was practicable. The

FIG. 1—SECTIONAL ELEVATION OF BUTRESS FOOTING ON CLAY

plant consisted of a 300-ton gyratory crushing unit, a 400-cu.yd. concrete mixing unit, a sawmill for heavy cutting, an engine house with one 50-hp. engine and a 75-hp. electric hoist, a machine shop, and a 40-hp. gas engine to operate rigging and an overhead cableway. The rock crushing and concrete mixing units were operated by electric motors and the bucket in No. 2 tower was handled by the electric hoist. Distribution of concrete was by towers and chutes. Two towers were required to chute to all parts of the dam, one at the mixing plant 160 ft. high and one on the dam 140 ft. high above the dam top. Fig. 7 is a view of the dam showing the towers. With this tower and chute system, concrete was delivered 500 ft. at the rate of a yard a minute.

Excavation and Handling Material.—The excavation was chiefly difficult because a great portion consisted of trenches in clay, shale and rock and had to be done by hand. In the deep trenches bracing had to be handled with care. The bulk excavation was performed by steam shovels and trains with some slip and Fresno scraper work.

All materials were brought to the dam over the construction railway down the canyon and were stored in yards, bins and sheds as indicated by Fig. 6. After the lumber was framed it was carried to the foot of the dam and then set in place by the overhead cableway. The reinforcing units were fabricated in the yard and

FIG. 5—DETAILS OF EXPANSION JOINTS

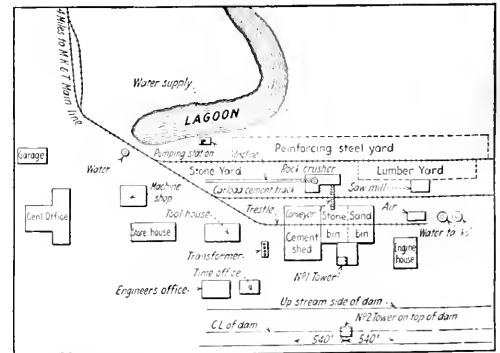

FIG. 6—GENERAL ARRANGEMENT OF CONSTRUCTION PLANT

FIG. 7—DAM UNDER CONSTRUCTION SHOWING CONCRETE DISTRIBUTING TOWERS

then handled as was the form lumber. Cement was chuted from the cars directly into a 2,200-bbl. cement house. All carloads of sand and crushed stone were unloaded by a clamshell derrick near the connection of the construction railway with the M.-K.-T. R.R., and then loaded into 16-cu.yd. dump cars which unloaded into the bins of the mixing plant. Most of the crushed stone, however, was quarried within a mile or two of the work and teamed to the crusher plant shown by Fig. 6.

Form Construction—Beams and buttresses being alike, forms were built in sections or panels. They were 2 x 8-in. sheathing on 4 x 6-in. timbers spaced 2 ft. on centers. The panels were tied together through the concrete by tie rods and form clamps. These panels were used from 20 to 30 times and some of them lasted through the construction work. The serious problem was the design and handling of the form panels for the deck slab face.

As shown by the plans (Fig. 1) the dam buttresses

FIG. 9—SHEATHING FORM FOR BACK OF DECK SLAB

FIG. 8—DETAILS OF DECK SLAB FACE FORM PANELS

were 18 ft. apart on centers. The expansion joints in the deck slab were 72 ft. apart, or over every fourth buttress, and the deck was required to be concreted in a succession of lifts continuous between expansion joints. As shown by Fig. 8 and the view Fig. 9, the form for the back of the deck slab was sheathing on beams spanning between buttresses. A very rigid panel was required to form the face of the deck slab as the span was 18 ft. and there could be no tie rods through the slab between buttresses. Ease of handling had also to be considered. A panel 2 ft. wide and 18 ft. long (Fig. 8) was designed by the authors. The rigid construction of the panel will be noted. After being set side by side up the deck as shown in Fig. 10, the ends of the panels were fastened down by the T-rails as shown by Fig. 8. Then they were clamped between ends by waling timbers held by truss rods as shown by Fig. 8.

Four bays of the deck between expansion joints were concreted at once in lifts several form panels high. This is clearly shown by Fig. 10. A 1:2:4 concrete was chuted directly into the forms by the chute arrangement, shown by Fig. 11. The method as described proved very successful. The panel forms were reasonable in cost, could be easily shifted and could be removed repeatedly without damage and used over again.

Construction Organization—The organization with E. M. Urban as superintendent in complete charge of all work consisted, besides workmen, of: 1 general carpenter foreman, 5 sub-foremen, 1 rigger foreman, 3 sub-foremen, 1 concrete foreman, 1 sub-foreman, 1

FIG. 10—CONCRETING DECK SLAB UNIT BETWEEN EXPANSION JOINTS

Using 2x18-ft. panels the sloping deck was concreted from bottom to top, in sections 72 ft. wide between expansion joints, by direct spouting into the forms.

crusher foreman, 1 steel foreman, 1 sub-foreman, 1 clamshell derrick engineer, 1 master mechanic and 5 labor foremen, directing various kinds of work. There were approximately 450 men employed, consisting of carpenters, riggers, iron workers, cement finishers, common laborers, hoisting engineers and mechanics for maintenance of equipment and machinery.

The working hours were from 7 a.m. to 6 p.m., making a ten-hour day. The living quarters consisted of a large headquarters building, with large airy offices on the second floor, and sleeping and living rooms on

the first floor. Comfortable cottages, fully equipped with water, electric light, etc., were furnished to families of foremen. A large mess hall and bunk house accommodated about 200 men. There was also a mess hall for Negro and Mexican labor, equipped with shower baths and lights. In fact everything possible was done to afford comfort and good and clean wholesome food for all employed on the job.

A North Sea Car Ferry

The successful operation of car ferry steamers across the channel between England and France during the war has led to establishing a car ferry across the North Sea from Harwich, England, to Zeebrugge, Belgium, to be operated in connection with the London & North-eastern Ry. and the Belgian State Railways. The advantages claimed are in economical and rapid transport, owing to the elimination of handling at the ports; also the saving of time, reduced cost of handling, small risk of breakage and pilferage, and saving in the cost of packing. A large business is expected in perishable goods, rolling-stock, locomotives and heavy machinery which otherwise could only be transported when dismantled and packed. Special facilities are granted by the customs authorities. The Great Eastern Train Ferries Co., of London, has purchased three steamers, each having capacity for fifty-six 10-ton freight cars on four tracks. One of the transfer bridges for connecting the dock with the steamer was lost at sea while being towed from Southampton to Harwich. It was supported on two barges, one of which sank owing to rough weather, and in going down it pulled the other barge over. It was expected that the bridge could be raised.

FIG. 11—CHUTE ARRANGEMENT FOR CONCRETING DECK SLAB

Concrete Road Built of Precast Slabs As Experiment

Slabs of Three Sizes Were Used in One Mile of 18-Ft. Pavement Laid on Adobe Marsh Land Near Suisun, Calif.

AN EXPERIMENTAL road of precast reinforced-concrete slabs has been constructed by the California Highway Commission at Suisun about midway between San Francisco and Sacramento. The purpose is to study methods of construction and costs as well as behavior in service, using three sizes of slabs and building some of the road of concrete in place for purposes of comparison.

The pavement was made 18 ft. wide and 6 in. thick throughout the job. Approximately one mile was constructed of precast slabs and about one-half mile was cast in place using concrete mixed at a central mix-

ing plant and hauled to the site in trucks. Most of the slabs laid are 9x9 ft. in size, but two short stretches are of slabs 6x9 and 3x9 ft., respectively.

All slabs were handled by means of lifting chains and hooks engaging cross rods of reinforcing steel in small holes cast in the slab. The 9x9-ft. and 6x9-ft. slabs have four holes each, a pair being located near each end at approximately the quarter point on the transverse dimension. The 3x9-ft. slabs were provided with two holes each.

Work of casting the three different sizes was carried on simultaneously.

Various types of reinforcing were used; some slabs have both mesh and rods, some contain rods alone and in others no steel other than the rods at the lifting eyes was used. The slabs were not moved until the concrete had been fully cured. The slabs were cast first, and while they were curing concrete from the mixing plant in the casting yard was hauled the two miles to the road and the cast-in-place pavement was completed. Of this half-mile, approximately one-third was constructed without expansion joints, one-third with elastite joints at intervals of 30 and 40 ft. alternately, and one-third was built with elastite joints similar to those last noted but with the addition of loose dowels passing through the elastite to prevent the pavement on one side of the joint from rising above the abutting section.

By the time the half-mile of pavement cast in place

THREE SIZES OF PRECAST CONCRETE SLABS ON SUISUN PAVING JOB IN CALIFORNIA

Two rows of the largest size slabs 9 ft. square, were used to make the 18-ft. roadway. The 6x9-ft. slabs were placed

With the 6-ft. dimension across the road, thus requiring three rows, and the 3x6-ft. slabs longitudinally in six rows.

ing plant and hauled to the site in trucks. Most of the slabs laid are 9x9 ft. in size, but two short stretches are of slabs 6x9 and 3x9 ft., respectively. All slabs were handled by means of lifting chains and hooks engaging cross rods of reinforcing steel in small holes cast in the slab. The 9x9-ft. and 6x9-ft. slabs have four holes each, a pair being located near each end at approximately the quarter point on the transverse dimension. The 3x9-ft. slabs were provided with two holes each.

The casting yard comprised four acres bordering on a spur track in the outskirts of the city of Suisun. The yard was laid out so that slabs could be cast flat in parallel rows, the rows being separated 2 to 5 ft. to afford space for runways. Side forms were placed and the subgrade in the casting yard was prepared as when pavement is to be cast in place on the road. Cross forms, however, were placed in order to make the slabs of the desired dimensions. In each row alternate slabs were cast and allowed to set for 24 hours after which the cross forms were removed, and after oiling the exposed concrete edges the remaining slabs were cast. After casting the ground layer, additional tiers were cast on top of one another to a total height of three tiers, single-ply roofing paper being used between tiers to prevent bond. The mix used was 1:2:4, and the slabs weighed approximately 1, 2, and 3 tons, respectively for the 3x9-ft., 6x9-ft. and

had been finished the precast slabs were cured and the operation of placing them was begun. The slabs at the end of the work nearer the casting yard were placed first, thereby permitting the use of the finished pavement over which to haul the slabs and avoiding any disturbance of the prepared subgrade.

Side forms were used in preparing the subgrade for the present slab section of the road as if the pavement were to be cast in place. The soil was first removed to a depth of 1 or 2 in. below subgrade and 1 or 2 in. of clean dry sand was placed and struck off to a true grade just in advance of the placing of the slabs. The pavement was laid on an old road bed which is a thin crust over marsh mud. The road traverses marsh lands at this point and the pavement itself is but slightly above the extreme high tides, hence the water table is very close to the subgrade.

The slabs were loaded, by means of a crane at the casting yard, onto the bed of the delivery truck. On arrival at the work the truck backed under a gantry crane spanning the pavement just over the last slabs placed. This crane picked up the slabs from the truck bed and delivered them to place on the subgrade. Three men were employed at the yard loading slabs and three men and a foreman in the road placing them. In addition one man was employed spreading the sand cushion and one man part time in setting forms. The maximum number of 9x9-ft. slabs laid in

a single day was 39, but due to lost time by rainy weather, wet subgrade, etc., the average day's run was only 23. The maximum run for the 6x9-ft. slabs was 37 and the average was 31 and the maximum for 3x9-ft. slabs was 60 and the average 48.

In the matter of placing, the 6x9-ft. slabs cost approximately 10 per cent more per linear foot of road than did the 9x9-ft. slabs. Had the work been more extensive, equipment better suited to the job might have been supplied, state highway officials stated, and the slab laying would have proceeded faster.

The slabs cost more than the cast-in-place concrete

SLAB BEING LOWERED TO PLACE BY GANTRY

The truck backed up under the gantry, workmen standing on the slab lifted it by means of the chain block and by the same means lowered it after the truck moved away. The 6x9-ft. slabs were handled by one man. The gantry crane was pulled ahead by one of the trucks using lines passed through blocks.

for the following reasons: (1) Slabs were reinforced and cast-in-place concrete was plain. (2) Slabs required extra formwork per cubic yard. (3) Slabs required practically two subgrades, one in the casting yard and the other at the road. (4) Slabs required a sand cushion, and were provided with elastite joints. These items, together with the hauling and placing of the slabs, made the cost of the slab pavement about \$10 per cubic yard more than for cast-in-place pavement.

Slabs were cast three deep in the yard. The upper two tiers were found to have thicknesses of sufficient uniformity so that simply lowering the slabs onto the sand cushion gave a smooth, continuous surface. The lower tier, which was cast on the ground, varied somewhat in thickness. After they had been lowered to place on the sand cushion it was occasionally necessary to raise them again and rework the sand.

Heavy loads have not been frequent over this road heretofore, but extensions now planned for the canneries at Suisun will probably cause it to be subjected to heavy loads of produce in the future.

Bank Foundation Designed to Resist Flood Uplift

Sub-basement of Mellon Bank, Pittsburgh, Built as Floating Box—Heavy Floor Transmits Upward Water Pressure to Columns

BY JOHN W. PICKWORTH

Welskopf & Pickworth, Consulting Engineers, New York City

PERIODICAL floods of the Monongahela and the Allegheny rivers at Pittsburgh led to certain difficulties in the design of foundations for buildings in the low-lying business district of the city. Much of the soil being a heavy gravel, the flood waters quickly spread to a considerable distance beyond the actual river banks, and where deep and dry basements are desired it is necessary to make adequate provision against the hydrostatic pressure in floods. This condition gave rise to a number of interesting problems in the design of the Mellon National Bank Building, now nearing completion. This solution is outlined briefly in the following.

The building, which is to be used solely for banking purposes, is about 232 ft. long on Smithfield St. and 120 ft. wide on Oliver Ave. and on Fifth Ave. It has four stories above street level, and two basements, the lower one being 9.61 ft. below the highest water level on record. A large portion of the floor in the rear of the building is 2 ft. lower and in various pits the hydrostatic head is still greater. The building is supported on concrete piers which go down to rock, 15 ft. below the sub-basement.

It will be seen from the cross-section, Fig. 1, that in addition to the side pressure on its basement walls the building must resist the upward pressure of the water on its base, amounting to over 700 lb. per square foot for the main part of the sub-basement. This appears a formidable condition when it is realized that except around the walls, which are far apart, the upward forces are greater than the normal dead-loads.

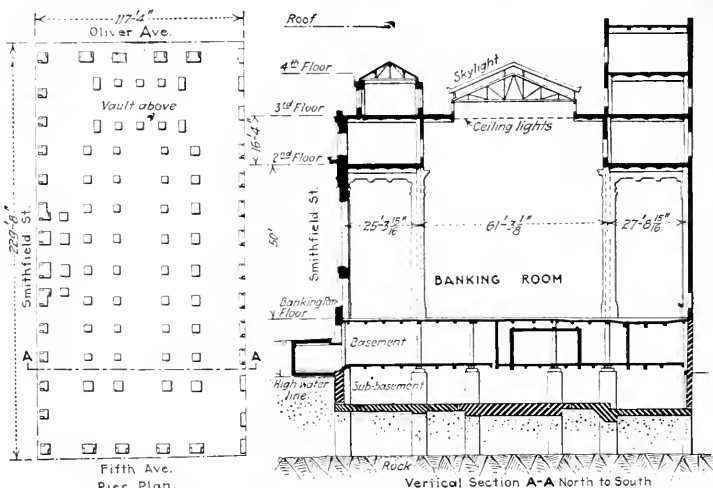

FIG. 1—NORTH-SOUTH SECTION AND PIER PLAN OF MELLON BANK

The floating-box construction of the sub-basement required on account of floods was complicated by the wide spacing of the columns. The banking room occupies the entire ground floor.

Foundations and Floor Anchorage—The security vault at the Oliver Ave. end of the bank rests on independent piers. The vault was constructed first, and enough of the permanent structure was built to house the vault and permit its use. Four wall piers and four interior piers of the main building were put in at the time the vault foundations were constructed, and, as it was then planned to carry all interior columns down to the sub-basement level, these four were constructed accordingly, as shown in Fig. 2. Hooked projecting rods were embedded in the piers, to engage the sub-basement floor and transmit the upward reaction from the floor slab to the piers.

Later it was decided to put in the rest of the foundations before tearing down the occupied buildings on the site. As the basements for these old structures

FIG. 2—INDEPENDENT VAULT IN EAST END OF BANK

At right is shown one of four building piers built at the time the vault was constructed, while the old building was still in use. The pier extends up to sub-basement floor level only. Hooked bars were built into the pier to anchor the floor slab, built later. All other interior piers of the building were carried up to the next floor above, giving more weight for resisting hydrostatic uplift; the sub-basement floor, built later, engages notches molded in these piers.

were not as deep as those planned for the new bank, the column grillages were designed to go in at basement level, and the sides of the piers were notched to receive the sub-basement floor, as shown in Fig. 3. Vertical reinforcing brings into action the full weight of the pier, as well as the column load above, as a reaction against the water pressure.

Sub-basement Floor—The sub-basement floor, of reinforced concrete, is designed to carry the upward forces in the most direct manner to the various points of load concentration from above. There is little dead weight in the central portion of the building, by virtue of the architectural layout of the banking room, which has but two main lines of interior columns, 62½ ft. apart. The banking room floor and the first basement floor were made of 6-in. stone-concrete slabs supported by steel framing, to add to the dead weight; concrete thus added is more effective than that used to thicken

FIG. 3—CONNECTION OF SUB-BASEMENT FLOOR TO PIERS AND RETAINING WALL

the sub-basement floor, because in the case of the latter every foot added increases the hydrostatic head by the same amount, and the only gain is the difference between the weight of the concrete and the weight of the water. Nevertheless it was necessary to make the central part of the sub-basement floor 4 ft. thick.

This part of the floor is designed with a cantilever extension of 3 ft., as indicated in Fig. 1, and the floor of the side bays is cantilevered out beyond the main interior columns to meet this first mentioned portion. The slab extends under the retaining wall, or else reacts against the notches left in the face of the wall piers. Concrete girders cast monolithic with the slab carry the upward reactions to the notches in the interior piers. At either end of the building the slab has a clear span of about 36 ft. and is 3 ft. thick.

Special slab, beam and girder construction is designed to take care of the elevator pits and the sump pit, which goes down to a depth of 7 ft. below the low

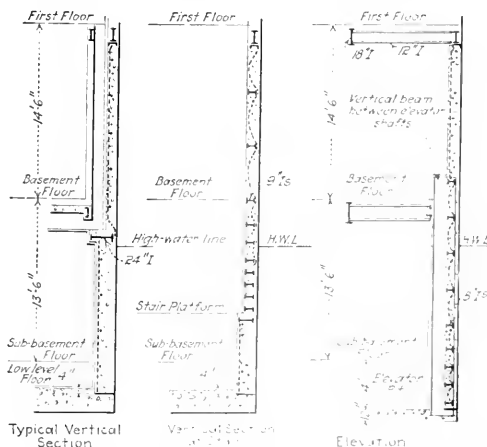

FIG. 4—THIN RETAINING WALL AT REAR OF BANK

FIG. 5—STEEL FRAMING AND SOME DETAILS
Banking-room column splice at third floor, and skylight supported on cantilever girders.

portion of the floor. The hydrostatic head calculated at the bottom of this pit is 19.61 ft., which means that the upward pressure exceeds 1,200 lb. per square foot.

The entire design of this floor lent itself to the establishment of good and proper lines on which to stop the pouring. The concrete contractor was asked to lay out the lines and areas that would best suit his convenience, and these were submitted to the engineers for approval. The various areas being entirely independent of each other, it was immaterial which portion was selected to be poured first, or how long it was necessary to delay the pouring of the adjacent section.

Retaining Walls—On the three street sides of the building the retaining walls in the sub-basement story are 3 ft. thick, and are designed to span as beams between the piers that carry the wall columns; 10-in.

seats are left in the piers for this purpose. The upward reaction of the sub-basement floor is in most instances more than balanced by the wall load, but where because of the sidewalk vault the weight is insufficient the retaining wall was doweled into the piers with 18-in. lengths of 6-in. I-beams, which make good dowels for shear and to which it is easy to fit the forms.

Along the rear lot line the retaining wall had to be kept much thinner. The typical section for the two basement stories is shown in Fig. 4. The wall is a vertical reinforced-concrete slab which throws its reaction against the sub-basement and banking-room floor levels. The 24-in. I-beam laid flat is so placed to allow passage for the ducts above, and it frames into the steel column shaft just above the level of the grillage. The accumulated horizontal pressure is then transmitted through the column and the girder connection to the whole of the floor system. Back of the stair and elevator shafts the wall had to be kept exceptionally thin; here structural steel framing was used.

Pier Design—Special care had to be taken in the design and detail of the concrete piers. On the three street sides the piers have to carry, in addition to their vertical loads, the horizontal reactions of the retaining walls and the forces on the outside faces of the piers themselves. To do this they are designed as cantilevers, using the heavy, sub-basement floor as a fulcrum point. Fig. 3 shows typical conditions.

Waterproofing—All the concrete for the sub-basement floor and the walls up to the curb level contains integral waterproofing compound. In addition to this, an inside coating of Cow Bay waterproof cement mortar is carefully applied under special specifications. This hydrolytic coating is $\frac{3}{8}$ in. thick on the walls and 1 in. thick on the floors.

Superstructure—The most interesting engineering features of the building superstructure (Fig. 5) are banking-room columns, which have an unbraced height of 50 ft., and the third floor framing, which cantilevers out to support the roof and skylight over the central portion. The high columns are of box section, made up of two 12-in. channels and 18-in. cover plates. To avoid having this large section run through the second floor to the splice line, which would necessitate extra furring and occupy valuable floor space, a special detail was made for this point, as shown in Fig. 5.

The 40x130-ft. skylight is supported on the ends of the 11-ft. cantilevers of the third floor; it has a heavy protective screen over it.

In construction, no difficulty was experienced from water. Had a high flood occurred before there was sufficient weight on the foundations to withstand the pressure, it would of course have been necessary to admit the water freely and let it flood the sub-basement.

Trowbridge & Livingston and E. P. Mellon are the associated architects for the bank. The vault and the first section of the building and the piers were constructed by the Hughes-Foulkrod Co., with the McCintic-Marshall Co. as subcontractors for the structural steel. The main building is being put up by the Mellon-Stuart Co. The Carlem Engineering Co. is the subcontractor for the reinforced-concrete work, and the American Bridge Co. for the structural steel. The design was made and the engineering services were rendered by the firm of Weiskopf & Pickworth.

Federal Land Reclamation: A National Problem

2. The Development of the West Under Irrigation

By C. E. GRUNSKY

C. E. Grunsky Co., Engineers, San Francisco, Calif.

The Second of a Series of Articles on the History and Performance of the Great Government Adventure in Irrigation of the Arid Lands of the West.

PROGRESS in the West under irrigation has been truly remarkable. Let us take a few concrete examples beginning with one of the most recent developments, the Imperial Valley. Perhaps the reader may not recall that the region now covered by the Imperial Irrigation District was known to the pioneer as the New River country, taking its name from one of the channels in which flood waters of the Colorado River occasionally flowed north into the Salton Basin. These waters came from the delta region of the river where, in Lower California, they submerged and wetted thousands of acres, where the rank vegetation showed that the desert of the Southwest could be converted into arable land if water could be brought to it. The scheme of Dr. Wozencraft and his associates in 1859 to have the U. S. Government give California 3,000,000 acres of lands in the southeastern part of the state for reclamation having been blocked—and perhaps wisely, because it would have been a premature enterprise—the desert areas of the Salton Basin, included in the region designated on the old maps as the Colorado desert, remained for many years a barren waste, treeless, without grass and repellent to every form of life. The project to irrigate this almost rainless area was revised in the last years of the last century and irrigation water became available there in 1902. Without dwelling upon the difficulties that had to be overcome, let it suffice to say that there are now about 450,000 acres of land under cultivation in Imperial Irrigation District, every acre of which requires water from the irrigation ditch; and, south of California in Mexico from the same canal system which brings Colorado River water into California, an additional area of about 200,000 acres is now being irrigated. The property value created in California by this one enterprise exceeds \$100,000,000. The annual crop output has a marketable value, not including the products of lands in Mexico, of more than \$50,000,000. The population of Imperial Valley has reached 60,000—an asset to our country that is certainly worth while.

San Joaquin Valley—Going further back contrast for a moment the situation in the San Joaquin Valley, also in California, as it was 60 years ago and as it is today. Here and there under natural conditions with rain generally 5 to 10 in. in a year there was grass for sheep and stock. In favored localities the early settler would even attempt to grow grain. The occasional year with moisture sufficient to produce a crop would prompt other attempts, but dry farming was not successful except to a moderate extent along the base of the Sierra Nevada at the eastern margin of the valley and northward from the Stanislaus River where there was a more dependable rainfall. The waters of Kern, Tule, Kaweah, Kings, San Joaquin, Tuolumne and Stanislaus rivers were at that time flowing unused to the sea. The population consisted of a few blacksmiths, the crossroads saloon-keeper, here and there the staff of a country hotel and

the sparse population of the frontier region centering in the widely scattered cattle ranches with pre-emptors and homesteaders in favored spots seeking some gullible speculator who would take their holdings off their hands. And now one finds prosperous communities from end to end of the valley made possible by irrigation. Of course, the irrigation commenced in a haphazard way with small ditches here and there, at points where diversions could be made from the stream with inexpensive works. But results were encouraging; the small individual ditch was soon replaced by larger ditches serving a number of irrigators. Commercial enterprises such as the great San Joaquin and Kings River Canal were started, though often, as in the case of this canal, they proved financial failures while in the hands of the original projectors. Later came co-operative enterprises with consolidation of irrigation systems with better, more dependable service, and finally the irrigation district, based on the sound doctrine of community enterprise, and ownership of the water rights by the land on which the water is used. To be a little more specific, Bakersfield, Tulare, Porterville, Visalia, Hanford, Corcoran, Lindsay, Dinuba, Reedley, Sanger, Fresno, Madera, Merced, Los Banos, Tracy, Manteca, Oakdale and many other communities owe their development and growth to the use of water by the irrigator. This growth can perhaps best be illustrated in figures.

There were invested in the irrigation enterprises of the San Joaquin Valley southward from Stockton in 1920, according to the U. S. Census, about \$69,000,000. The land under cultivation by irrigation in this part of the valley in the same year had an aggregate area of over 2,000,000 acres. The population of this region already exceeds 250,000.

Southern California—Still greater is the progress made under and due to irrigation, in that part of California generally referred to as Southern California. The need of irrigation in this semi-arid region was early recognized. The development thereof as noted in the citrus industry, the growth of San Bernardino, Riverside, Redlands, Pasadena, Los Angeles and San Diego, which may be cited as typical, would not have been possible without the utilization for irrigation of the water resources of the southern section of the state. In the central and northern portion of California the value of irrigation was not so early recognized because nature furnishes to these more northerly areas a more bounteous rainfall. But now the advantage of applying water to the land by artificial means to supply deficiencies and to prolong the growing season is apparent to all, and the demand for irrigation water is constantly on the increase. The natural flow of even so mighty a stream as the Sacramento River no longer suffices. Regulation of flow by storage is becoming imperative.

As in California, so elsewhere in the West, in Washington, in Eastern and Southern portions of Oregon, in Idaho and Montana, in Wyoming and Colorado, in Utah

and Nevada, in Arizona and New Mexico, in all of these states the development under irrigation has been little short of marvelous—to say nothing of the growing of rice in the Gulf States.

Government Aid in Irrigation

The early irrigation works were of the simplest type, easily constructed at trifling expense. When the water had to be taken to points remote from its source, to lands less favorably located than those covered by the first canals, co-operation became essential. Mutual water companies were organized and many commercial or speculative ventures were undertaken. Presently it was found that the natural low water flow of the streams would not longer suffice to meet the demand of the growing irrigated area. Recourse must be had to storage in order to regulate the stream flow and to conserve the waste at the flood stages. Government aid was enlisted. The states began a study of their water resources. The formation of irrigation districts was authorized. The Congress of the United States, too, saw the need of encouraging the reclamation of desert areas and made provision for the same in the

under consideration about 40 per cent while in the Mountain and Pacific states, as shown in the table, the population more than doubled.

The figures in the second table, also taken from Census statistics, will show that irrigation is widely practiced and has contributed in large measure to the marvelous prosperity of the country already shown by the figures in the first table.

Financial Benefit of Irrigation—In the 19 most westerly states including Arkansas and Louisiana there had been invested in irrigation enterprises over \$321,000,000 in 1910 and over \$697,000,000 in 1920. In these states, considered together, about 9 per cent of the improved farm area was irrigated. In Arizona about 65 per cent of the improved land is irrigated. For California this percentage is approximately 35, for Colorado 33, Idaho 55, Montana 15, Nebraska 2, Nevada 95, New Mexico 31, Oregon 20, Utah 80, Washington 7, and Wyoming 58.

The value of the principal crops produced in 1919 on the irrigated lands of the eleven Western states is given in the United States Census as \$702,441,166. Through the farmer this sum finds its way to the

TABLE 1—DEVELOPMENT OF THE FARMING INDUSTRY, 1860-1920: MOUNTAIN AND PACIFIC COAST STATES (IRRIGATION STATES) COMPARED WITH UNITED STATES AS A WHOLE

	1860	1900	1910	1920

* These figures are given for the year preceding the census year. They do not include live-stock products.

Carey Act. As a final means of stimulating home-building on the irrigated farm, government aid has been extended throughout the West under the provisions of the United States Reclamation Act passed in 1902. Over \$135,000,000 has been expended by the U. S. Reclamation Service in the construction of works many of which could not have been undertaken without government aid. All of this has been a powerful factor toward the development of a part of the world ideally adapted to support in comfort a dense population.

Stimulating Effect of Irrigation—The examples above cited are crudely illustrative. Perhaps a few figures relating to the growth of the West under the stimulating influence of irrigation will give a better picture of past achievements and of the progress still being made (Table I). The states included as irrigation states in the summary presented in this table are: Montana, Idaho, Wyoming, Colorado, New Mexico, Arizona, Utah, Nevada, Washington, Oregon and California.

From such statistics as presented in this table, compiled from the U. S. Census, it appears that while the value of the farms in the entire United States was four times greater in 1920 than in 1900 the value of the farms in the Mountain and Pacific states was six times greater in 1920 than in 1900. The value of the farm products in the entire country was four times greater in 1920 than in 1900 while in the Mountain and Pacific Coast states under the stimulating influence of irrigation the value of the output of the farms was eight times greater in 1920 than in 1900. The population in the entire United States increased in the twenty years

transportation agencies, to merchants and professional men, to educational institutions, to amusement places and some goes for taxes. It is fair to assume that what the second man gets goes to a third within a month, and so on, making the volume of business that results in a year from the activity of the irrigators in these states appear at many times this amount. Here, then, is a clear indication of the influence of irrigation upon the development of the West.

Future Extension of Irrigation

On the subject of the amount of water that remains available in the streams for new enterprises and the extension of irrigation systems already in service it is interesting to note what is said on this subject in the U. S. Census of 1920: "Taking the western part of the United States as a whole, with few exceptions, the low water flow of the streams is exhausted, but there is a very large supply of flood water available for storage. There is no lack of tillable land on which this water can be used. Future extension of irrigation depends on whether economic conditions are such that the value of the crops which can be produced will justify the expense of storing the flood waters."

It must not be forgotten, furthermore, that the permanency of the irrigator's business depends upon his being able to get more for his crop output than it costs him. Not, of course, all the time but dependably, based on average conditions. There is, therefore a cost limit, varying according to many factors such as character of crop, access to market, the hazards of produc-

tion and other elements beyond which he cannot go in providing irrigation works. It is not to be wondered at that he welcomed government aid in the extension of irrigation to projects that presented somewhat greater difficulties than had to be overcome by the early settlers who selected favored locations. Nor is it sur-

TABLE II—NUMBER AND CAPACITY OF IRRIGATION WORKS

Drainage Basins	Main Num- ber	Ditches Capa- city Sec.-Ft.	Reservoirs Num- ber	Capa- city Acres-Ft.	Pumping Pumps Num- ber	Capa- city Sec.-Ft.

prising that there are many who even with government aid have not been able to keep their farm and family expenses within the limit of crop returns and who in consequence would rather have the United States give them a still greater bonus, than admit defeat and surrender their holdings to some one better equipped to produce results. The bonus which it is intended should go to the irrigator under the U. S. Reclamation Act is given indirectly. It is the difference between what the irrigation works would cost if undertaken by the farmer as a private or community enterprise compared with a charge to him by the United States at cost without interest on the deferred payments. Estimated at 5 per cent interest, the irrigator is expected to pay only about 55 per cent as much under the Reclamation Act for his irrigation system as he would pay for the same if it were constructed without government aid. If interest during the construction period and interest on the investment during the development were taken into account the bonus would appear still higher than these figures show. It should be remembered in this connection that the intended bonus did not always go to the present owner of the land. Whatever increment of value was added by the construction of the government irrigation system would naturally be retained by the preceding owners, where there had been any, and this value was no doubt in many cases overestimated. The present owner, in such circumstances, may have an extra burden to carry which, however, he has voluntarily though sometimes unwisely assumed.

Overproduction and the Time Element—Periods of overproduction of farm products such as that through which we are now passing with resulting low prices, are discouraging to the farmer and we find in consequence that the question is asked with increasing frequency, Why extend irrigation still further? Why add still further to the surplus of farm products which cannot be disposed of? The answer is simple, though of course not entirely satisfactory, that the periods of overproduction, regardless of causes to which they may be due, are recurrent and that the farmer will again come into his own within a few years. It must not be forgotten that time is an important factor to take into account when the merits of any project for the further exten-

sion of arable and particularly of irrigable lands is under consideration. For the full development of a large irrigation project 10 to 30 years should be allowed. This time allowance, moreover, is reflected in the estimated cost and may become a material factor. In such large proposed projects as that of the Columbia Basin and that of the lower Colorado River where irrigated areas are talked of in millions of acres, this is particularly true. These are projects involving the regulation and control of streams which are of the interstate type. On such streams the United States should provide or should in any event control the works for the regulation of flow, and before undertaking or authorizing construction should be satisfied that the proposed projects are feasible, not alone from engineering considerations but also from the economic standpoint. Can the power and the water be disposed of at prices that will return fair interest on the investment? This is the test and this test cannot be fairly applied without a proper consideration of the time element.

Cost of Water Rights—And now a word as to what the irrigator can afford to pay for water. Some 30 or 40 years ago so-called water rights could be bought in various parts of California. These water rights entitled the holder to some fractional part of the water in a main or branch canal and were paid for at a fixed price per acre or per unit of the canal flow. In the San Joaquin Valley, California, the price of \$10 per acre soon became almost standard, it later went to \$20. It could be considered either as a bonus paid by the irrigator to the canal owner or as an advance payment of rates. The water right contract usually runs with the life of the canal company and is therefore limited in duration and usually carries with it an obligation to make annual operation and upkeep payments in definite amounts per acre. The price fixed by the canal company for the water right was generally intended to reimburse the company for its capital outlay, but sometimes, due to limited demands for water rights, this was very slow in coming in. In southern portions of California, where the need for water was greatest and benefits largest, the crop output being valuable, and where the natural flow of the stream in proportion to the available land was unusually small, the water rights were soon at \$1,000 to \$2,000 per miner's inch, or \$50,000 to \$100,000 per second-foot, representing an investment for water of \$150 to \$300 per acre.

The early practice of canal owners was to confine construction of the irrigation system to the main canal and principal branches, letting the farmers build as they might such laterals and distributing ditches as they needed. This fact is to be taken into account in comparing costs of systems as constructed early in the history of irrigation with recent costs for systems, complete, with delivery of water to each small holding.

It is not possible to give with any degree of precision the amount per acre which the land owner can afford to pay for irrigation water. Much depends in this connection on the location of the land, its adaptability to produce crops under irrigation, upon transportation facilities and similar factors and also upon the value of the land before irrigation water is made available. If arid land is in question which is almost without value until irrigated, the increment of value added by the irrigation canal may be relatively large. In the case of land already in use with sufficient rainfall to warrant the planting of grain crops the amount which the owner

can afford to pay for irrigation water may be considerably less than when arid land is to be irrigated. As a general proposition the irrigator of diversified crops can afford an annual outlay including interest on the investment of \$5 to \$10 per acre for irrigation water, the larger amount only, however, if the irrigated lands include a large proportion of vineyard, orchard or truck gardens. Where there is but little truck gardening and the area in orchards and vineyards is small an expenditure for a gravity system of irrigation works in excess of \$80 per acre will be justified only in exceptional cases.

When irrigation is accomplished by pumping, interest on the first cost of the installation may be but a small fraction of the cost of the water. The main element of expense, depending upon the head against which the water is pumped, will be the power and attendance required at the pumping plant. Favorable conditions as to crops that can be grown and favorable market conditions may, of course, warrant a large annual outlay for the operation of such a pumping plant, but here again special studies should be made of each particular situation whenever the estimated cost of the service per acre including interest on the investment goes over \$5 or \$6.

Precast Concrete Cribbing for Retaining Walls

Units Placed Easily and Quickly—Drainage and Foundations Simplified—Extensive Use in Railway Work

CELLULAR retaining walls of precast concrete units, as an economical development of the common practice of using old ties and timber for temporary cribbing to restrain the slopes of fills, are being employed in a number of cases, since increasing cost of construction work has emphasized the economy of such permanent crib walls as compared with timber cribbing or even with solid retaining walls. Different types of concrete units have been developed and numerous structures installed under severe conditions have demonstrated both economy and satisfactory service. Concrete crib walls of the "Interlock" type, shown in Figs. 1 and 2, with details in Figs. 3 and 4, are being used by several railroads and industries.

In this type of cribbing there are three forms of precast pieces, designated as headers, full-length stretchers and half-length stretchers (see Fig. 3). Ordinarily only the first two are used, the half-length stretcher being employed occasionally where a wing wall with plumb end is desired. Their steel reinforcement is furnished built-up ready for placing in the forms. These concrete units are installed with one or two parallel rows of longitudinal stretchers supported transversely by the headers, but for comparatively low walls only one row of stretchers is required. It will be noted that the longitudinal unit or stretcher is formed with a supporting member at the middle, thus

FIG. 2—CONCRETE CRIBBING RETAINS TOE OF FILL

allowing the vertical joints to be broken or staggered without the necessity of additional blocks or fillers. The ends of both stretcher units are recessed so as to interlock with the T-head headers.

The large crib wall shown in Fig. 1 forms a bench for an inclined industry track in the slope of a main track embankment about 33 ft. high, on the Chicago track elevation work of the Rock Island Lines. Here the cribbing, 10 to 13½ ft. high and with a face batter of 1 in 12, rests on a fill supported by a retaining wall approximately 20 ft. in height, which was built prior to the installation of the cribbing. Some of the half-stretchers will be noted in the end bay, between the headers and the bridge abutment. This crib wall built into the fill was adopted instead of a second retaining wall, since the latter would have involved great cost for a solid wall either on pile foundations or with masonry extending to the ground. The low-level bridge for the industry track was not in place when the view was taken. Similar construction has been employed on the Detroit track elevation of the Michigan Central R.R., but with both the upper and lower walls built of cribbing.

The Chicago installation, made under severe foundation conditions, has been in service more than seven years and it is reported that in addition to great saving in first cost the service results have justified its use. Although the embankment settled considerably during the first year after the wall was constructed, the flexibility or elasticity of the cribbing allowed the units to adjust themselves without detrimental effect to the stability of the wall. Other crib walls were built on the same project and with such success as to lead to

FIG. 1—CRIB RETAINING WALL ON ROCK ISLAND LINES; CHICAGO

Topped retaining wall 26 ft. high. Crib wall 13½ ft. high, set back 14 ft. from lower coping. Industry track at foot of cribbing and main tracks at top.

FIG. 3—UNITS FOR CONCRETE CRIBBING

the adoption of this system by engineers on other works. In general, the cribbing is used for retaining or restricting the slopes of fills, but it has been applied also along the toes of wet and sliding cuts. A crib toe wall on the Chicago track elevation work of the Illinois Central R.R., shown in Fig. 2, is at the Main St. bridge at Matteson. In this case, the headers are not staggered and no half-stretchers are employed, as in the arrangement shown in Fig. 1.

These precast units are of sufficient length to take care of the wall heights commonly required and can be handled by common labor without the use of special equipment. The high wall in Fig. 1 was built by a foreman with four laborers. The units are placed as the filling proceeds and are not built up to any considerable height in advance of the filling. By this method and by eliminating the usual period required for the placing and curing of poured concrete there is considerable saving in time. The theory and practice of design are similar to the case of solid walls, but owing to the uniformly distributed dead load and to the rectangular section causing the embankment pressures to be applied at a greater distance from the face of the wall, the toe pressure is reduced to a minimum and the latitude of uses for cribbing on relatively soft foundation soils is increased materially.

Advantages claimed for the concrete cribbing include: Low first cost of construction, speed of erection, use of unskilled labor, adaptation to congested territory, ample drainage of wet filling, freedom from frost troubles, distribution of load on soft ground, flexibility of

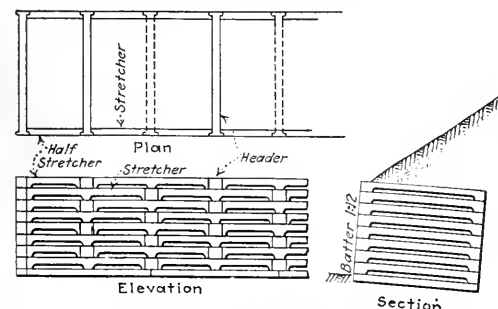

FIG. 4—CELLULAR CRIBBING OF CONCRETE UNITS

design to allow of its use without foundation construction, small number of types of units, and salvage value in case of reconstruction or a change in height of wall. This type of structure is considered to be adapted particularly for temporary or permanent use on railway and highway work where reduction in cost and time of construction is important, or where it is desirable to avoid such interference with traffic as might be involved by poured concrete construction. It is applicable also in various other cases, as in walls at industrial plants, an example of such work being the construction of walls to retain a coal stockpile at a manufacturing plant. The concrete units may be made by contract or by railroad forces at any convenient point.

Conveyors Handle Clay at British Port

BELT conveyors for handling china-clay and loading it into steamers are a feature of a new pier at Fowey, on the south coast of England, which is an important shipping port for this material. In 1922 more than 600,000 tons of clay were shipped, largely to the United States. The pier or jetty extends at a sharp angle from the river bank, so that it has a berth 300 ft. long on one side only. Steel cylinders sunk to rock and filled with concrete support a frame of steel girders having brick arches between them and a concrete deck 50 ft. wide. Freight cars of 10 and 12 tons capacity, having the ends hinged at top, are run upon a tilting table at the shore end of the pier and dump the clay into a circular chamber 34½ ft. in inside diameter and 23 ft. deep. As this chamber, supported on foundation cylinders, extends below the water, it is made with a 33-in. concrete wall between two steel shells.

A hopper in this chamber feeds the clay upon an inclined conveyor belt traveling at 125 ft. per minute and rising to a height of 35 ft. above the pier. At the top, the clay is delivered by a transverse belt to a horizontal belt extending the full length of the pier. This belt serves a loading tower which travels along the berth side of the pier and has an inclined adjustable chute to deliver the clay into the ship's hatches. A revolving shoe or spout at the end of the chute spreads the falling clay and reduces the amount of hand trimming of the cargo in the hold. The conveyor galleries and the tower provide for duplicate equipment of belts and chutes when required. To handle clay shipped in barrels and sacks there is a 3-ton revolving crane traversing the top of a gantry traveling on the berth side of the pier and between the shipping tower and outer end of pier. Storage for twenty cars is provided on a side-track and the cars are moved to and from the pier by cables and capstans. The dumping table, conveyors, tower, crane and capstans are all electrically operated. This shipping plant was designed under the direction of W. W. Grierson, chief engineer of the Great Western Ry., and was built by the Cleveland Bridge & Engineering Co.

Los Angeles Holds Out for Breakwater

Los Angeles interests already are taking steps looking to congressional sanction for their plan to construct a breakwater to provide shelter for Terminal Island. It is regarded as unlikely, however, that Congress will override the Chief of Engineers and the Board of Engineers for Rivers and Harbors, who have reported emphatically against the breakwater plan.

Formation of Transverse Fissures in Steel Rails

An Abstract of James E. Howard's Latest Report to the Interstate Commerce Commission Together with a Discussion by C. A. Morse, J. L. Campbell, C. R. Harding, and J. M. R. Fairbairn

Since the transverse fissure was first identified in 1911 as a specific type of fracture, railroad engineers and steel-rail manufacturers have been endeavoring to discover the cause and to find some means of preventing its development. James E. Howard, engineer physicist of the Bureau of Safety of the Interstate Commerce Commission, has probably done more than anyone else toward discovering

the cause of this perplexing type of fracture. His latest report sets forth his views as to the cause. Knowing that many men do not hold the same views an abstract of his report was sent to a number of engineers with request for an expression of opinion. The replies from four of them, from widely scattered parts of the country, and an abstract of Mr. Howard's report are given below.

Transverse Fissures in Steel Rails and Their Prevalence on Certain Railroads

THE REPORT of Mr. Howard summarizes available data and gives illustrations of transverse fissures and a number of diagrams made from a tabulation of the rail failure reports of various railroads in this country. The new data brought out by Mr. Howard show: The location of rails which fail by transverse fissures according to mileage, on certain sections of railroads, the heat numbers of such rails and the number in each heat, the position in the track (such as the high or low rail on curves), the number of fissures displayed according to years and months, according to ingot position, and according to year rolled.

The known facts concerning transverse fissures which the report brings out are: Transverse fissures have an interior origin starting from a nucleus a few hundredths of an inch in diameter. A silvery crescent next forms, concentric with the nucleus, which increases in size until the periphery of the rail is reached. The surfaces of the fissures present a silvery luster until air is admitted. They occur in both Bessemer and open-hearth rail and in all weights of rail up to the heaviest rolled. They have been found in rails from every rail mill in the country. Fissures always occur in the head of the rail and in larger numbers on the gage side. On curves they occur more frequently on the inside rail, and on railroads having both light and heavy tonnage tracks they occur more frequently in the heavy tonnage track. In fact, on one railroad a large number have occurred in the heavy tonnage track and none have occurred in the light tonnage track. They occur in new rails and in rails thirty years old, in rails rolled in every year for which records have been kept, and in all ingot positions. Some of the earliest failures have occurred in rails coming from parts of the ingot generally conceded to be the best. Nor do bending stresses appear to cause the fissures, for incipient fissures have been found $1\frac{1}{2}$ in. from the end of a rail and fully developed fissures $7\frac{1}{2}$ in. from the end. They have occurred in some of the best track in the country and in some of the poorest, and at all seasons of the year.

So-called shattered zones have been found in rails of the harder grades of steel, located in the central part of the head or base or at junction of the base and web, but these zones do not extend to the hot-sawn end of the rails. A definite relation between these shattered zones and transverse fissures has not been established, but transverse fissures have been found with their

nuclei located in the sound metal between such shattered zones.

In addition to the known facts reviewed in the text of the report the diagrams bring out three things which have not been so clearly indicated before. They are: (1) That certain heats seem to be more subject to failures by transverse fissures than others. (2) That on practically every railroad submitting reports on this type of failure, the failures seem to be grouped in certain geographical positions, so that in any one piece of track the failures will occur at certain mileages in considerable number while at other mileages there will be few or no failures. (3) That rails rolled by certain mills in certain years are much more subject to failure by transverse fissure than rails rolled in other years. This latter condition is emphasized by the fact that the reports from different railroads show similar conditions for corresponding years. For example, for the year 1910 Bethlehem rails on both the New York Central and the D. L. & W. show an unusually large number of failures.

Year of Rolling—As to failure of rails in the same year, the author says that at least in the case of the Great Northern Ry. the rails which displayed transverse fissures in large numbers were very hard rails in respect to chemical composition and were intended to offer great resistance against abrasion. He adds that: "Notwithstanding the doubt which has been expressed in regard to certain years' rollings, no identification of defects has been announced upon which the belief is founded. In due course of time it will be of interest to see whether those years of mistrust occupy a certain place in regard to the calendar, or whether they advance and maintain a more tangible relation to traffic conditions."

No deductions are made by the author from the fact that failures by transverse fissures are concentrated at certain locations in the track on the sections of railroads used for the tabulation. Nor does he add any data to show whether this feature is merely the result of physical conditions such as might occur on the inside of sharp curves with high elevations, or whether the personal factor is responsible, or whether rails from heats which seem to be subject to transverse fissures were concentrated at those points.

In his review of the facts concerning transverse fissures the author discusses each one in its relation to the various hypotheses of their formation which have been advanced since his discovery and discussion of this peculiar type of failure in his report on the Man-

chester wreck in 1911. The ingot position of the rail as a primary cause is eliminated by the fact that failures occur in rails from all parts of the ingot; age is eliminated by the fact that transverse fissures have developed in rails a few months and many years old. He questions the evidence that rails rolled in certain years are more subject to transverse fissures, and says that the evidence is not sufficient to show that the fissures are due to other than unusually hard steel or to density of traffic.

Causes—Mr. Howard states that certain heats display greater durability than others. He points out that the internal strains due to cooling and gassing are shown to have little possible effect on the formation of transverse fissures, that the so-called shattered zones are probably the result of cooling strains, and that although there may be some connection between transverse fissures and shattered zones the fact that transverse fissures have been found in the sound metal between two shattered zones would seem to indicate that they were due to some other cause. The cause of transverse fissures is, he thinks, the internal strains set up in service by the cold-rolling effect of the wheels. The result of this cold rolling is to set up intense strains of compression in the shallow zone of metal at the top of the rail which develop a counterbalancing tension on the central part of the head. The strains of tension find relief in the formation of transverse fissures, but this is temporary, and as the cold rolling continues similar strains are built up in the adjoining metal until other fissures occur. This formation of two fissures in close proximity would be impossible under the action of bending stresses alone. The author then proceeds to show how in laboratory tests transverse fissures have been produced under conditions approximating field conditions. Track stresses as a primary cause are also eliminated by the fact that transverse fissures have occurred in all weights of rail and on all kinds of track.

The report draws attention to the fact that transverse fissures are practically unknown on English and Continental railways and points out that from what is known of the manufacture of foreign rails and the conditions of their acceptance, it does not seem probable that the practical immunity from transverse fissures is due to superiority of the metal used. The moderate wheel loads are a significant factor.

In his concluding remarks the author says:

Three features constitute the rail problem: (1) Girder strength; (2) Abrasive resistance to the action of wheels; (3) Cold-rolling effect of wheels on the head of the rail. If the third feature was eliminated, there would be no rail problem, since the requirements of the first and second can be met without difficulty. The third feature is the vital one, and admits of solution in one way—by the proper regulation of wheel loads. The effect of wheel pressures, as they are received by the zone of metal at the top of the head, constitutes the essence of the rail problem. Internal strains which tend toward the formation of transverse fissures are acquired by all rails. Selection of the proper grade of steel and the regulation of wheel loads constitute factors for meeting their influence.

Inasmuch as the adjustment of wheel loads, according to the ability of steel to endure them, is not a flexible matter, it is left to ascertain what grades of steel possess maximum durability under current track conditions.

It is reasonable to believe that a specific and remediable cause may be found for the failure of some rails, notably those which fail prematurely, revealing whether abnormality resides in the steel, in the tracks, or in the wheel

pressure. It is questionable whether increased weight of rail, far beyond the heaviest now being rolled, would overcome the destructive effect of these fissures.

Rock Island Results Not In Entire Accord

By C. A. MORSE

Chief Engineer, The Chicago, Rock Island & Pacific Railway Co.

IN ORDER to study transverse fissure rail failures on the Chicago, Rock Island & Pacific Ry. in their relation to traffic density and to axle loads, we have superimposed the data concerning transverse rail failures upon a tonnage diagram.

A study of this diagram shows that the transverse fissures have predominated with us on 100-lb. rail in our heaviest traffic territory, but it also shows 19 transverse fissures, four heats of which had three or more transverse fissures develop, occurred on our Arkansas Division in a territory where we have single track and where the combined east and westbound traffic is a little more than 9,000 tons a day. It also shows on that same division two transverse fissures where we had about 8,000 tons per day, but the point where we had 34 transverse fissures was on our westbound track with 18,000 tons a day; 25 fissures on our eastbound track where we had 22,000 tons a day, and 16 fissures on a single track where we had nearly 23,000 tons a day on one track, yet just adjoining this last piece was a stretch of 32 miles, 22 miles of which were single track, on which we had nearly 25,000 tons passing over the one track with no failures.

This would indicate possibly what Mr. Howard contends—that the majority of the transverse fissures are on heavy traffic lines and that heavy rail does not prevent them; but I do not think that the diagram substantiates Mr. Howard's claim with reference to heavy wheel loads as our lines between Chicago and Rock Island, where we have the most business and the most transverse fissures, has a lighter axle load than much of the territory west of that where we have developed transverse fissures, and on our Arkansas Division east from Memphis, where we show 21 transverse fissures, one section having an axle load of 53,000 lb. and the other 45,750.

Density-of-Traffic Theory Not Supported on El Paso & Southwestern

By J. L. CAMPBELL

Chief Engineer, El Paso & Southwestern System

THE THEORY that the transverse fissure or its incipency is not in the rail when laid but is made in its incipency and its development by the rolling of the wheels on the rail, is unsupported by satisfactory evidence. Mr. Howard says that the number of transverse fissures is greatest on those roads where the traffic is heaviest, and appears to conclude from that that the theory above described is correct. Is this theory supported by observation of the fact, if it exists, that the greatest number of rail failures through transverse fissures observed to occur on tracks carrying maximum traffic are uniformly distributed throughout the length of such track and as between all kinds of rails on that track? The theory needs the support of observation.

On the El Paso & Southwestern, a line of comparatively light tonnage but approaching the maximum in speed and axle loads, we have had only one definite instance of pronounced trouble with the transverse fissure. This occurred on 25 miles of 85-lb. open hearth Bethlehem rail laid in 1908 and removed in 1921 on account of continued rail failures, all of which showed the transverse fissure normally located in the center of the head. The first failure occurred shortly after the rail was laid, derailling a light special train running 50 miles an hour, the rail breaking into six pieces and all fractures showing the fissure. The last failure was a

few months before the removal of the rail began. Except as the rails removed may have had incipient or developed transverse fissures, of which there was no indication on the surface, they were all in excellent condition and adequate for continued service.

East and west of and connecting to this 85-lb. rail was rail laid on the east in 1909 and 85-lb. rail laid on the west in 1912. From these dates until the 85-lb. rail failing through transverse fissure was removed from the track, all of the 85-lb. rail on that district carried identically the same traffic but no trouble from transverse fissures developed in the rail laid in 1909 and 1912. The latter rail is still in the track and in good condition.

Should Improve Rail to Meet Present Requirements

By C. R. HARDING

Consulting Engineer, Southern Pacific Co.

JAMES E. HOWARD'S latest contribution to our knowledge of interior transverse fissures in steel rail is a remarkable step toward the final solution of this old and baffling problem.

One thing which has gone far toward maintenance of railway service at low rates in this country is the operation of heavy units of power and long heavily loaded trains. The material at present available for steel rails is in some way deficient, when it comes to resisting cold rolling strains due to heavy wheel loads.

There will probably be larger and better units of power and equipment developed in the future, but it would seem prudent to pause for a while, in the matter of unit weights, to permit rail steel to catch up with present-day requirements.

The field is wide open for our metallurgists, to discover a material, method of manufacture or method of heat treatment which will provide proper resistance to cold rolling effects without detriment to other functions demanded of steel rails. The Southern Pacific Co., for one, following its practice of long standing, would undoubtedly purchase liberal amounts of rail of a material which seemed to promise the above results. As a large user of rails this company would thus encourage the manufacturers to help toward the desired end.

Geographical Distribution on the Canadian Pacific

By J. M. R. FAIRBAIRN

Chief Engineer, Canadian Pacific Railway Co.

AS THE 39 transverse fissures on the Canadian Pacific were distributed over all the districts on both Eastern and Western Lines and came from 17 different divisions, 20 different subdivisions, and 32 sections it is apparent that they are not seriously bunched geographically and that our campaign to educate the section foremen to recognize a transverse fissure has been effective. The information is not offered as a refutation of the statement that transverse fissures are bunched geographically on other railways, but is simply a statement of the facts as they have so far developed on the Canadian Pacific Ry.

I am convinced that if we are not now securing reports on all of our transverse fissure failures we are at least securing reports on the great majority of them and that no considerable number escape identification. We are, however, continuing our educational campaign.

Columbia River Bridge Tolls

Tolls from the bridge over the Columbia River between Portland, Ore., and Vancouver, Wash., totaled \$224,223 for the first nine months of 1923, according to a report of the Interstate Bridge Commission. This exceeds the figures for the corresponding period last year by about \$49,000.

Through the Reclamation Country

By F. E. Schmitt

Associate Editor, Engineering News-Record

A SERIES OF ARTICLES on Federal Land Reclamation is now running in *Engineering News-Record* the second article appearing in this issue.

The purpose of the series is to give a history of the twenty-one years of government irrigation, state the many problems of operation—engineering, agricultural and financial—analyze the various complaints that are being so emphasized by those who are seeking a reform of the current law and methods and seek to present some views as to a constructive policy in the future. Through it all will run the evident theme that irrigation, from planning, through construction to operation, is a continuing engineering problem.

As a part of the preparation of the series Mr. Schmitt is now traveling through the West, visiting irrigation projects, studying developments and interviewing builders, operators and settlers. He is writing this series of letters of running comment on the situation as he sees it on the ground. These are not the final result of his trip but they will serve to acquaint our readers with the actualities of reclamation as revealed to an unprejudiced investigator.

This is the fifth letter. The first appeared in the issue of October 4.—Editor.

San Francisco

INTERVIEWS with bankers and other men informed about financial conditions among the farmers on reclamation projects bring out the fact that these farmers have money troubles. They are heavily in debt, have not been finding it easy to pay interest, and want more credit.

Financial Difficulties—On several northern projects the mortgage indebtedness on the farms averages \$40 to \$70 per irrigable acre of the whole project. Most of this is in real estate mortgages at 8 to 10 per cent; the rest is in chattel mortgages at rates up to 12 per cent. There are also crop obligations every season, not included in the above. Thus a yearly interest charge of \$5 to \$7 has to be paid out of the earnings of each acre. The average gross production of the projects, however, is sometimes as low as \$25 per acre, and does not exceed \$50 under favorable conditions; in fact, the best one of these northern projects produced only \$48 per acre as the average of the last seven years, and only \$27 in 1922, a year of abnormally low prices. Out of such earnings as this the farmer must pay all costs of production and in addition must pay \$2½ for taxes, \$1½ to \$2 for water, \$5 to \$7 for mortgage interest and \$1 to \$4 for construction-cost installment; and he ought to have enough left to pay him a wage for his labor.

One might figure that the farmer doesn't need a wage, that he gets a living out of his farm over and above the reported crop production. Doubtless many farmers do; but on one project, at least, town store people have remarked with surprise on the number of farmers who buy eggs, milk and other food supplies that they should raise on the farm—and of course this means more money to be taken out of the crop sales.

With such a narrow margin between income and outgo as these data indicate, the farmer is pinched in the ups and downs of crops and prices. When heavy crops and good prices come together he can make some money, but unless he is prudent enough to save for

future losses, the lean years may ruin him. All the time it is mainly the mortgage debt burden that keeps him down in the mire.

Farm finance is one of the biggest elements of the reclamation problem, in fact. The Congressional relief acts and departmental postponements of charges, where they have been of any use at all, have not touched the matter of getting and keeping the farmer out of debt, or (on the principle that a certain number of fleas are good for a dog) down to the desirable amount of debt.

The expense of pioneering has largely been worked out on the reclamation projects. The heavy debt burden did not come from this expense but from the ballooning of land values four or five years ago and the resulting land speculation. The poorest projects were least hit by this inflation, and are least in debt now.

Bankers admit quite freely that they were carried away in the short post-war boom; they admit that they loaned far too freely, loaned too much per acre, and helped along the value-inflation. There were shoestring purchases of land, where most of the small cash payment was raised at the bank on first mortgages and the seller took a second mortgage for the bulk of the price, a proceeding which imperiled all three parties. Much land changed hands at valuations on which it could never pay except with abnormally high prices for crops and these prices collapsed soon after the boom in values. The bankers' ideas of land values were quite as optimistic as those of the farmers. Bankers as well as farmers have been paying the penalty during the last three years.

Land Values and Government Equity—One might suspect some fundamental flaw in the habits of mind that allowed these effects to come about, and such a flaw appears to exist, in fact. There is a peculiar thing about land values on reclamation projects: they take no account of the government's equity in the property. The unpaid construction charge is simply disregarded. Farmers buy and sell without regard to this equity, tax assessors make their valuations in the same way, and bankers loan in the same way. Only the Federal Land Banks deduct the government equity from appraised clear value (and then loan up to half the remainder). Though they have been operating for only about a year on the reclamation projects, they are helping to make other bankers' ideas sound. But even now a certain bank that is called conservative has loaned without question nearly twice as much per acre as the Federal Land Bank limit for the particular reclamation farms concerned, and this in cases where the Land Bank absolutely rejected the loan on account of its moral hazard.

One natural result of basing credit operations on such loose-thinking is that the government equity comes to be considered unreal, or is forgotten; and a secret feeling springs up that in all fairness the Reclamation Service ought to forget it also. But another result, and perhaps a more serious one, is that the settler is enabled to cash in on the full land value, and thinks he is justified in doing so, despite the fact that he is appropriating an element of value which the nation at large created, a loan not yet paid. In thus putting the government equity into his own pocket when he sells, he burdens the purchaser with an extra debt, usually on top of an already inflated land value.

The individual settler cannot be blamed greatly for such actions, since they are in line with the general practice in his community. The blame properly rests on the system of the law or its administration. If the main objective of reclamation is the development of stable farm-home communities, the farmer should have full right to the productive value which his labor develops in the land, but he should be prevented from trafficking in the value created by the government's irrigation enterprise until after he has paid for it. The California State Settlement rules contain safeguards for accomplishing this but federal reclamation practice lacks them. I understand that a first attempt in this direction is about to be made in a new contract form devised for the Yakima project.

Speculative Selling and Settling—Besides the speculative element in selling and loaning on the reclamation projects, there seems to be a large speculative factor in the original settling. Farmers, bankers and irrigation operators in private as well as in government service have told me that a large number of the settlers, probably more than half, come originally with the main idea of getting something for nothing. Some of these speculative settlers farm, some few farm well; but many become absentee landlords, and either let their land lie idle or have it farmed, after a fashion, by renters. Some projects are spotted with such idle or poorly farmed units, and it is not specially comforting to learn that this piece is held as a speculation by a former United States senator, or that one by a slipshod town garage man, neither of whom will ever get into the farm-home class. If resale were hindered until after the government equity is paid for, possibly there would be fewer speculative settlers.

From the figures given as to the farmer's debt and payments it can be seen very clearly that the water charge and the construction charge are *not* the things that make or break him, as might be thought from some of the grumbling at these charges. No feasible reduction of these charges would save the farmer who by lack of skill or unthriftiness is going down, and no ordinary increase would wreck the one that is making a success. But the farmer sinking under the excessive weight of his debts will grasp at the straw of the government charge.

A Continuously Moving Railway

A "never-stop" railway, a new type of line for local passenger traffic, in which a number of small independent cars are moved by a longitudinal screw with varying pitch of thread, is being exploited in England and is a development of a scheme invented in the United States many years ago. At stations the pitch is small so that the cars move slowly and passengers can step in and out; beyond the stations the pitch increases gradually to the maximum for high speed. A short line has been built in an amusement park at Southend by the Never-Stop Transit Co., Sardinia House, London. The cars are operated independently instead of in trains, and each has beneath it an attachment with rollers engaging the thread of the screw between the rails. This screw or shaft is carried in ball-bearings and is rotated at constant speed by means of motors which may be as much as 1,200 ft. apart. For this system it is claimed that it requires no signals, brakes or trainmen.

Water-Works Dam Withstands Record Flood

Oklahoma City Structure Passes Almost Five Times Designed Capacity, Though 250 Ft. of Corewall Fails

FLOOD waters that reached a peak toward midnight of Oct. 15 and which, it is estimated, more than doubled the June record flow in the North Canadian River at Oklahoma City, Okla. (see *Engineering News-Record*, Aug. 23, p. 292), poured over the city water-works dam with a maximum height of 27 in. over the dam crest, inundated all the surrounding country, and finally scoured the downstream face of the corewall until a section about 250 ft. failed, emptying the reservoir without damage to the dam, except slight injury to the handrail in one or two bays, replacement of which cost about \$50. It is estimated that at least 65,000 sec.-ft. of water passed over the dam and through the control works, though the designed spillway facilities, depending upon the head, are from 12,000 to 15,000 sec.-ft. Other damage to the water-works, all of which it is estimated will cost \$1,200,000 to repair, include the loss of gunite slope paving to the reservoir of two 500-ft. sections and the carrying away of about 500 ft. of the bypass embankment at the upper end of the bypass canal.

The general property damage to Oklahoma City through the flood, caused by excessive rains, will ap-

proportionately be less than at Oklahoma City. Preceding the recent flood, the rains began Friday, Oct. 12 and lasted through Monday, Oct. 15, during which time 5.29 in. had fallen in Oklahoma City. The rainfall west of Oklahoma City, up the river valley, was even heavier than at Oklahoma City.

The flood crest first manifested itself at Woodward, Oklahoma, on Oct. 13, thence it passed rapidly down the valley, reaching El Reno, forty miles west of Oklahoma City, Sunday afternoon, Oct. 14, and the Oklahoma City reservoir, seven miles above Oklahoma City, before midnight, Oct. 15. At 9:25 o'clock p.m. the earthen embankment at the west end of the dam gave way and the resulting flood wave crest passed through Oklahoma City from 11 p.m., Oct. 15, to 3 o'clock a.m., Oct. 16.

General Damage—The damage to railroads, street railway and highway can be best appreciated by the fact that no traffic of any kind was able to cross the North Canadian River from midnight, Oct. 15, until Robinson Avenue was re-opened at 4 o'clock p.m., Oct. 18.

The street railway lost all three of its bridges, together with probably two miles of track and fills. The bridges were all pile trestles, one of which had been carefully replaced after the June flood.

AIRPLANE VIEW OF OKLAHOMA CITY AFTER FLOOD
Water had fallen about 3 ft. when this view was taken.

SURFACE CAR TRACK TORN UP

proximate \$2,500,000, not including the damage to the water-works. Report of the flood and damage to the water-works is given by V. V. Long, consulting engineer of Oklahoma City, who made an examination of the works and prepared a report at the request of *Engineering News-Record*. His report follows:

The year 1923 has made flood history for Oklahoma City. The yearly rainfall has been to date 42.5 in., while the average yearly rainfall is 31.5 in. Yet during this year there have been four floods of the North Canadian River, with stage heights and estimated maximum flow as follows:

May, 15,000 cu.ft. per second; June 13, 33,000 cu.ft. per second; September, 12,000 cu.ft. per second (height 14 ft.); and Oct. 15, estimated, 60,000 cu.ft. per second. The maximum flood of record previous to this year was 11,000 cu.ft. per second, in October, 1920.

The North Canadian River has a long, narrow valley with a tributary drainage area of 10,000 square miles above

The Santa Fe R.R. bridge, a steel span with pile trestle approaches, stood the flood with water several feet over the track, but the railroad embankment at both ends went out for a total length of approximately one mile.

The Frisco R.R. lost two pile trestle bridges and several miles of track as the heavy current of the flood passed through their east yards.

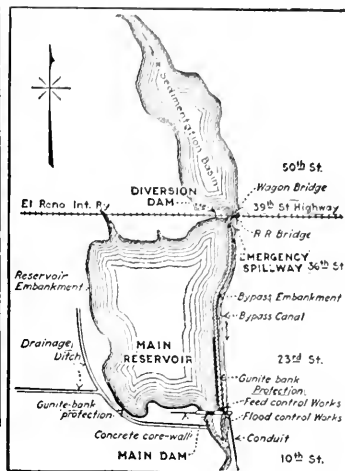

The Rock Island Railroad lost its pile trestle bridge west of the city, but the steel spans of both the Rock Island and M., K. & T. railroads east of the city stood the flood, although considerable track of both lines went out.

Damage to Water-Works—The Oklahoma City water supply suffered probably the largest damage; however, there has been no interruption of service. The water lacked only 6 in. of reaching the pump and boiler room floor levels.

The Oklahoma City water reservoir covers 1,700 acres with a storage capacity of 7,000,000,000 gal. and is formed by an Ambursen dam 54 ft. high above shale, across the North Canadian River, about seven miles above Oklahoma City. At the west end of the dam, a concrete corewall resting on sheetpiling driven to shale, extended from the end of the Ambursen structure some 500 ft. westward. Around the south and west sides of the reservoir west from the dam an earthen fill varying from zero to probably 6 ft. in height was thrown up for a roadway to an elevation uniformly equal to at least 12 in. above the walkway on the Ambursen dam, which walkway is 6 ft. above spillway of the reservoir. For over 6,000 ft. west from the west end of the dam the reservoir banks are protected with gunite slope paving 3 in. thick, with a 4-in. gunite wall, the top of which comes up to an elevation 12 in. above the walkway on the dam. This same protection extends for over 4,000 ft. along the reservoir side of the

AIRPLANE VIEW (AFTER FLOOD) AND PLAN OF DAM, RESERVOIR AND BYPASS

bypass embankment which follows the east side of the main reservoir.

The bypass canal is 120 ft. wide at its base with 2:1 slopes and is approximately two miles long, with an 18-in. fall. The embankment between the canal and the main reservoir is protected with good 12-in. riprap on the bypass side, and with the gunite on a 2:1 slope on the reservoir side.

The bypass was originally intended to carry all flood waters by the reservoir through four gates 9 x 14 ft. and a spillway 72 ft. long by 5 ft. deep at the east end of the main dam. These are computed as having a carrying capacity of 12,000 cu.ft. per second. There is an emergency spillway from the bypass to the main reservoir near the upper end of the bypass, which together with the gates to the main reservoir at the lower end of the bypass have a normal capacity of 9,000 cu.ft. per second. Near the west end of the dam there are four gates 4 ft. by 5 ft. and a spillway 144 ft. by 6 ft. deep through the Ambursen dam out from the main reservoir to the river below. The total flood capacity through the dam from both bypass and reservoir is between 12,000 and 15,000 cu.ft. per second. The June flood of 33,000 cu.ft. per second topped the walkway of the dam, throughout its entire length of 1,200 ft., 6 in. deep, but the gunite slope protection west from the dam, being 12 in. above the walkway of the dam, held the flood waters, and very little damage was done.

Bypass Embankment Broken—The flood burst through the bypass embankment into the main lake at about 5 o'clock p.m. just below the emergency spillway, carrying away about 500 ft. of the bypass embankment and filling the reservoir. The water kept rising until at 9:25 p.m. it was flowing over the walkway of the dam 27 in. deep, and was therefore 15 in. over the gunite slope protection and earth embankment west of the dam. At 9:25 p.m. the

break occurred in the corewall adjoining the west end of the dam, when approximately 250 ft. of the earthen bank and corewall gave way. While it is not known just how the break started, as it was dark and raining, it is thought that the water, flowing over the gunite and embankment, carried away the earth below the corewall, which then failed due to the pressure from above.

At about 5 p.m. both the street railway and the highway bridges at Thirty-ninth Street across the upper end of the bypass went out, and while every effort possible was made to catch all the debris therefrom, a portion of these bridges came down the canal and lodged in the gates and bypass spillway under the walkway, thus cutting their capacity down to probably 40 per cent of their rated capacity. Another portion passed into the main reservoir through the break in the embankment, and coming on through the reservoir, lodged in the main reservoir spillway under the walkway.

Failure of Gunite Protection—The gunite slope protection has stood the test with two exceptions, both of which are on the bypass embankment. At one place it is evident that something has hit the top of the wall, possibly a part of the bridges coming down from Thirty-ninth Street, this crushed some 500 ft. of wall. Near the dam, about 500 ft. of the gunite on the bypass embankment slid down after the water drained out of the main reservoir. It is quite evident that this was caused by the saturated bypass embankment which was not stable on a 2:1 slope.

It is not known how much the reservoir capacity has been cut down by silting up due to the flood passing through, as this can only be determined by soundings and surveys.

These floods have shown that the bypass canal and the spillway and gate capacity of the dam are woefully inadequate.

BREAK IN COREWALL; NOTE POINT AT WHICH IT JOINED DAM, WHICH WAS UNDAMAGED

UPPER END OF BYPASS CANAL

Both highway and interurban bridges, latter the El Reno Int., were washed out.

The writer is indebted to C. E. Bretz, water superintendent of the Oklahoma City water-works, for the water-works pictures, and a large part of the information relative to the floods and reservoir failure. Mr. Bretz was personally in charge of the work of attempting to save the reservoir and worked heroically, almost without rest, from Saturday to Tuesday, and by his untiring efforts the water service in Oklahoma City continued without interruption. The writer is also indebted to Warren E. Moore, Commissioner of Public Works of Oklahoma City, for the information relative to the situation in the city.

Mr. Stewart's Report—Spencer W. Stewart, president of the Ambursen Construction Co., engineers and builders of the Oklahoma City water-works dam, arrived in New York Oct. 29 after a special trip to Oklahoma City to inspect the dam. At the time of the flood his company was engaged upon a redesign of the dam, made after the June flood, which was to take care of a maximum flow of 63,000 sec.-ft. over spillways and through flood-control gates. The contract for this extension was made Sept. 15. The increased flowage was to be secured by opening eight bays in the dam at about a third of the way from the east end of the dam and placing crest gates, and by lowering the crest level in the existing ones. Four more gates of the same size as will be placed in the dam will be placed in the bypass spillways, thereby allowing for a maximum flood discharge there of 18,000 sec.-ft. The gate-controlled pass at the upper end of the bypass will be opened to pass into the main reservoir a maximum of 50,000 sec.-ft. from the sedimentation basin. These improvements will be carried forward.

Closure of the gap, resulting from the failure of the corewall, will be made, asserts Mr. Stewart, by the con-

struction of an Ambursen spillway section about 350 ft. in length turned downstream at an angle of about 20 deg. to the axis of the main dam. Besides large crest gates this section will contain two 12x12-ft. caterpillar gates which will allow the reservoir to be emptied quickly and in advance of any flood waters that may threaten the dam. This latter betterment is contained in a report to the city authorities by the engineers in charge of estimating reconstruction needs.

Mr. Stewart made an examination of the reservoir and dam after flood waters had receded and he asserted that the failure of the corewall was due to the scouring of earth downstream from the corewall. He also said that both the railroad and highway bridges at 39th St., above the dam, were underscored, part of the highway bridge hitting the dam near the flood-control house being in a single section about 250 ft. in length. This length of bridge was practically intact when it reached the dam, the pile bents, decking and flooring all remaining as one self-contained section. As it hit the dam part of it rose in the air and turned over on the dam crest. Mr. Stewart said the failure of the gunite was perhaps due to the fact that with the reservoir water level much lower than that in the bypass canal after the corewall failed, seepage through the bypass embankment tore the gunite out, the hydrostatic pressure being too great for it to resist.

Dissolves Cement Manufacturers Protective Association

Judge in New York District Court Says Open Price Association in Eastern District Was in Restraint of Trade

JUDGE John C. Knox, of the United States District Court, Southern District of New York, on Oct. 23 ordered dissolved the Cement Manufacturers Protective Association as an illegal combination in restraint of trade. This was a decision in a suit in equity, brought by the United States requesting a decree dissolving the association.

The Cement Manufacturers Protective Association was formed in January, 1916, with a membership of eighteen portland cement companies operating in the Eastern states. Similar associations were also formed in different sections of the country. It should be noted, however, that none of these associations has any connection whatever with the Portland Cement Association, which is an association of practically all the cement companies in the country for technical purposes. According to Judge Knox's statement in the case, the Eastern association was formed with the following clause in its constitution:

The objects of the association are the collection and dissemination of such accurate information as may serve to protect each manufacturer against misrepresentation, deception and imposition, and enable him to conduct his business exactly as he pleases in every respect and particular, free from misdirection by false or insufficient information concerning the matters following, to wit:—(a) information concerning credits; (b) information concerning contracts which have been made for the delivery of cement, sufficient y complete to enable the manufacturer to protect himself against spurious contracts and like transactions induced by misrepresentation; (c) information concerning freight rates on cement; (d) statistical information as to production, stocks of cement and clinker on hand, and shipments.

BYPASS SPILLWAY AND GATEHOUSE

Debris clogging spillway and gates is partly timber from bridges at upper end of bypass canal

Association Activities—The judge then goes on to outline the operations of the association. He states that it undertook the collection and distribution of information on accounts outstanding, bills receivable, accounts in attorney's hands for collection, contracts made and in effect, contracts cancelled, a statistical statement of production and shipments during the preceding month and stock of cement and clinker on hand, and finally the preparation and distribution among members of a complete schedule of freight rates on cement, giving rates for rail, water, and rail and water shipments. Judge Knox then calls attention to the so-called "specific job" contracts, which are agreements whereby a manufacturer is to deliver in the future the cement to be used in a specific work, such as a particular building or road, and the obligation is that the manufacturer shall furnish, and the contractor shall take, only such cement as is required for or used for the specified purpose. In the year 1921, such contracts covered about 30 per cent of the annual cement production of all the defendant corporations.

Reference is then made to the bag-refund practice common among all cement companies and to the practice of basing all prices on a common mill basis.

In commenting upon the various procedures, the judge calls attention to the use of the freight rate books. He said that the publication of freight rates is obviously harmless, but that their vice resides in the fact that there is a concert of action upon the part of defendants in so using them that all prices quoted are for delivery at the point required by the purchaser, and that no cement will be sold in such manner as will permit a purchaser to take advantage of cheaper transportation charges than are required to be paid for the shipment of cement by rail. In extenuation of the practice, it was claimed that this method of marketing cement is a trade custom which came into being before the formation of the association, and is in no way to be attributed to agreement or any activity of the association.

Similarity to Early Association—The Judge says: "Very probably there is no agreement now in force by which such practice is to be followed. The custom, however, was at one time the subject of an agreement to which thirteen of the corporate defendants were parties, namely, the Articles of Association of Licensed Cement Manufacturers, dated June 30, 1909. This agreement, whatever may have been the justification for its existence, obligated each licensed dealer therein to observe certain practices, which if they were now the subject of contract, would without doubt entitle the government to the relief sought. It is not without interest to note the similarity existing between the uniformities and facilities now availed of by defendant corporations, and the practices observed by a number of them under the license agreement, which seem to have then been regarded as helpful, if not essential, in an endeavor to maintain prices and to apportion territory."

Judge Knox then cites a number of extracts from the proceedings of the association which, in his mind, tend to show that the object of the statistics was to provide each manufacturer with information regarding the business of the other manufacturer so that there would not be any wide variation in prices. The companies wanted to know the prices that the other companies paid for returned bags, which seemed to the judge to be an indication of the possibility of rebate in this system

which the association was anxious to prevent. He criticises further, somewhat mildly, the specific job contract prices, which he thinks were mainly to make assurance doubly sure that over any future time there would be no "free cement."

He devotes some attention to the contention of the defendant that in such a commodity as cement, uniformity of price is bound to result in an open market, but he contends that in the cement industry, where there is a marked difference in production cost, in the financial necessities of manufacturers, in the location of mills as respects active markets, and where there is less than a capacity production by all manufacturers who desire to sell cement, it is reasonably to be expected that there will be a difference in the inducements to be offered to prospective purchasers. He said that in a purely competitive market, producers would not be content with a situation wherein the field of competition was limited to the personality of the salesman, which is, the judge believed, the case in the cement business today.

Judge Knox admits the contention of the defendant that ignorance is not a virtue and knowledge and information are not a crime, but he says that in this case the sources of wisdom and knowledge are not open to all interested persons upon more or less equal terms, and that the customers were not possessed of the same information as the producers were.

Summary of Ruling—Finally the judge concludes in the following words:

There is, I take it, no need to find that the prices at which defendants sold cement during the period over which the association has functioned, were excessive. Indeed, as compared with the rise in the prices of other basic commodities, it is possible to say that the quotations of cement advanced less than others. Nor can it be said that the association overcame and destroyed all competition between the defendant manufacturers; upon many occasions, they were active in an endeavor to take business from companies associated with them. In some instances, they undoubtedly offered inducements to purchasers and thus secured orders that otherwise would not have been obtained.

But, upon the whole, and without further discussion of the great mass of evidence which goes to make up this record, I think that real competitive effort tended to become more and more feeble, that manufacturers by reason of the exchange of statistics, were equipped to regulate their production, and by common consent and a concert of action, did so, to the end that the cement supply would at all times be a lap or two behind the demand, and thus created higher prices. In enabling this to be done, the association, its officers and agents, together with its membership, materially limited the full and free operation of the contending forces of competition to which the public, under the Sherman Law, is entitled, and unreasonably affected interstate trade and commerce.

In conclusion then Judge Knox states: "The government may have the decree for which it asks."

Changes Made in Washington Warehouse

The reference to the refrigeration in the article on the Terminal Refrigerating & Warehousing Co.'s warehouse in Washington, on p. 633 of the Oct. 18 issue of *Engineering News-Record*, should read "Refrigeration is provided by four compound motor-driven ammonia compressors which produce 450 tons of refrigeration; 1,100 hp. is required to operate the plant when running at full capacity, including elevators and all miscellaneous machinery." Plaster was applied to the insulation work with a trowel instead of a cement gun as originally proposed.

Structural Lessons Learned from Survey of Steel-Frame Buildings After Japan's Earthquake

Wilbur S. Sample, Engineer for Fuller Co., Inspects and Reports on Condition of American-Built Structures in Tokyo—Recommends Design to Resist Shocks

JAPAN'S earthquake of Sept. 1 failed to destroy—although it damaged slightly—the three large steel-frame office buildings which the George A. Fuller Co. of the Orient, a subsidiary of the New York firm of the same name, built in Tokyo a year or two ago. After the quake Wilbur S. Sample, engineer for the Fuller organization in Dairen, Manchuria, went to Tokyo and on Sept. 19 and 20, in company with Japanese architects and engineers, he inspected the N. Y. K., the Japan Oil and the Marunouchi buildings, all steel-frame structures seven to eight stories high. A thorough examination was made of the damage resulting from the earthquake, extending to every part of each building, from basement to roof inclusive, that could be seen without further demolition of standing work. The following report covers Mr. Sample's findings and recommendations for the first two buildings above named, a separate report on the Marunouchi building being substantially the same as the one below quoted. Additional data from the Marunouchi report are included in brackets. Otherwise the text below applies to all three structures:

Structural Steel—The steel frame in every case seems to have been of sufficient strength to withstand the dead loads and the sudden application of any superimposed loads due to vibrations caused by the earthquake and also seems to have shown a sufficiently high elastic limit to have returned to its original position in every case. That there was undoubtedly a marked momentary deflection laterally in the columns is evidenced by the shattering of a large percentage of the masonry piers surrounding or enclosing the exterior wall columns and of the plastered partitions between the steel columns of the interior. While the momentary and violent deflection of the columns laterally, particularly in the second and third stories, was of sufficient strength to shatter the enclosing or contiguous masonry, the agitation was not sufficient permanently to distort the columns in any case.

[In the Marunouchi Building the report notes "the distortion or destruction of the steel cross bracings which were added to the structure after the earthquake of 1922."]

Reinforced Concrete—Except where the principal bays or sections of the parts of each building joined together, such as the front wings or the side wings, there was no evidence of any destruction or distortion of the reinforced-concrete floor slabs. At the joints between the front and side wings there were some minor cracks in the floor construction showing through the corridor floor surfacing, and indicating that the several sections of the building vibrated independently from each other, the cracks being undoubtedly due to a very severe shearing stress at these points.

Where gravel reinforced-concrete walls were used on the interior and on spandrel walls there was a minimum amount of damage.

[In the Marunouchi Building "there does not appear to be any marked or serious damage to the reinforced-concrete floor slabs or beam coverings. Where reinforced-concrete walls were used on the interior there was a minimum amount of damage except at certain points on stairway walls near the west side of the building. This damage was probably due to the lack of continuity of these walls in a straight line."]

Masonry Piers—In practically 90 per cent of the exterior piers of the second and third [and "fourth," in case of Marunouchi] stories there was evidence of a violent lateral motion or vibration of the entire structure; this extended to

a slighter degree to the piers of the first story and of the fourth ["upper," in case of Marunouchi] story. Above the fourth story there appears more or less destruction of exterior masonry but not nearly so pronounced as in the lower stories.

There appears to be no particular kind of facing material outstanding as successfully resisting the crushing and distorting effects of the lateral movement. Architectural terra cotta, cut stone, granite, stucco and tiles showed varying degrees of stability in the order given, the most successful being the last named.

Interior Partitions—The interior partitions in general are constructed of hollow clay tiles, metal lath on steel furring, concrete or reinforced concrete, all plastered on both sides. The hollow tile seems utterly unable to withstand the crushing effect of the lateral movement of columns, as evidenced by the crushing and falling of this class of partitions where the vibration was greatest or in the lower stories. In certain locations where metal lath partitions were used there was more or less damage but this damage was not nearly so pronounced as in the hollow clay tile partitions.

The concrete partitions behaved in a little better manner and the reinforced concrete partitions seemed to be the best of all, but there were some cases of a shattering of these by shearing horizontally along the center line of height, this occurring in partitions built of slag concrete.

Lighting Fixtures—The lighting fixtures in general were of brass canopies with opalescent glass globes, suspended from the ceilings by chain about 2 ft. long. The majority of the glass globes were destroyed by oscillating to such an extent as to strike the ceilings.

Marble Trim and Wainscoting—A portion of the marble finish of walls and columns in the first story was dislodged and destroyed, but as this work was done in the usually accepted manner there can be no thought of faulty workmanship.

IN CONCLUSION

After the San Francisco earthquake of 1906 I attended many meetings of architects and contractors held to discuss various building materials and methods of construction with a view of adopting such as seemed to be the best suited for stability. Practically all of the reconstruction work in that locality was based on designs and materials similar to or the same as those used in Tokyo in recent years, and I believe the Tokyo buildings constructed by your company would have withstood the shocks of an earthquake of the same degree of severity as the San Francisco earthquake, with a minimum amount of damage.

Now comes the Japan earthquake of 1923 with such unprecedented severity and such a tenacity of violence that it becomes necessary for us all to readjust our ideas of construction methods and to adopt such designs and take such precaution as in our belief will provide a greater measure of stability for future structures and a consequent added security for the lives of those occupying them.

With this thought in mind I beg leave to submit for your consideration the following recommendations as to the design of buildings to be erected in locations subject to earthquake shocks:

RECOMMENDATIONS

Foundations—A close observation of the effects of the recent earthquake in Tokyo induces the belief that all foundations should be of friction piles capped with reinforced concrete, isolated pier spread footings, or a solid concrete mat without piles.

In the case of friction piles a number of test piles should be driven of different lengths and in several locations on the lot, each pile tested as to its bearing capacity and each foundation computed from the data thus obtained, allowing

a safety factor of 6 or 7. In no case should the piles be driven to hardpan or to refusal. Each cluster of piles should be capped with reinforced concrete and these caps connected at the top in each direction with reinforced-concrete struts.

In the case of isolated pier spread footings load tests should be taken in several parts of the lot at the proposed level of the footings and the size of each footing computed from the data thus obtained, allowing a safety factor of at least 5. These footings should be connected in each direction with reinforced-concrete struts.

In computing the loads to be carried by either the pile footings or the isolated pier spread footings only the actual dead-load of the structure should be used. No live-load should be figured, or at the least only a very small percentage. Care should also be taken to have the bottoms of all footings at the same level, and deep basements should be avoided.

In the case of a solid concrete mat foundation the mat should be of sufficient thickness and figured for reinforcement to withstand the actual pressure on the ground as determined by computation of dead-loads, and should project sufficiently beyond the outside columns to avoid eccentric loading.

The foregoing recommendations are due to a belief that the soil underlying Tokyo will act as a sort of shock absorber as evidenced by the behavior of such buildings as Seiyukai Building, the Imperial Hotel, and the several other office buildings in Marunouchi. If the foundations or the piling under them are of such length as to reach solid strata then the full severity of the earthquake shock is transmitted through the foundations to the entire structure, while if the foundations rest on a soil of somewhat resilient nature the transmission of shock will be very much less.

Structural Steel—Columns should be placed in straight lines in each direction so that at every panel there will be a maximum number of points of resistance. The sections of columns should be as wide as possible in each direction and should be connected at each floor by girders as deep as the requirements for head room will permit. Both columns and girders should be latticed if the computation of stresses does not require solid web plates. If solid webs are required then the webs should be punched at frequent intervals to permit of the proper application of reinforcing steel as will be hereinafter discussed. Between the girders at each floor will be necessary steel beams for carrying the reinforced-concrete floor slabs.

In cases where head room or clear interior spaces are absolutely necessary then resort must be had to knee braces. It is recommended however that such rooms as absolutely require great height or clear interior be placed on the top story or as near thereto as possible. Rivets for connection of girders to columns should be in shear, wherever possible. Rivets in tension should be studiously avoided.

Reinforced Concrete—In all cases the specification for the mixture for reinforced concrete should be made after a study of the screen analysis of the coarse and fine aggregates available for use. No assurance of success can be had by the adoption of arbitrary proportions for the materials to be used. The water content should also be carefully considered and only a sufficient amount of water used to enable the practical working of the concrete into the forms.

Exterior piers around steel columns should be of reinforced concrete and as large as possible, extending from the frames of openings on each side and from the heads of window frames below to the sills of window frames above.

Interior columns and connecting girders should be entirely covered with concrete, thoroughly reinforced around and through the columns and longitudinally.

Build solid reinforced-concrete walls wherever possible between columns in the interior and also around such places as elevator shafts, stair wells, pipe shafts and vent shafts.

Wherever possible build solid reinforced-concrete walls from basement to roof and from outside to outside walls of building, leaving only such openings as are absolutely necessary for ingress and egress and reinforce the perimeters of such openings in a thorough manner.

Exterior Facing—Avoid the use of brick or stone veneer if possible, using only stucco work or thin tiles. Forming the outlines of projecting cornices, belt courses, etc., as largely as possible in reinforced concrete.

Partitions—If impracticable to use reinforced-concrete partitions the next best in the order named are metal lath on steel studs, solid brick, hollow brick, hollow clay tile. Reinforced concrete is, of course, recommended because of the additional stiffness thereby awarded to the structure as a whole, but if this seems to be impracticable then use metal lath.

Lighting Fixtures—Lighting fixtures should be either indirect system secured flat against the ceiling or should have stiff suspension.

Marble—Use a minimum amount of marble slabs if the marble is to be attached to walls or columns.

Separate Roadways for Commercial Trucks

BY ALEXANDER HOWARD NELSON

Engineer for Atlantic County, Atlantic City, N. J.

ON ACCOUNT of the interstate feature of automobile traffic, and probably because of discrimination through the variation in the fees being charged by different states, the whole matter of motor-car license fees might very well be taken over by the federal government and the net receipts distributed among the various states in direct proportion to license values.

Determination of the actual damage done by trucks can very accurately be arrived at by methods somewhat similar to those employed last year in the Bates experimental road tests in Illinois. Having determined damage and used it as the maximum fee, it would be a comparatively simple matter to plot a mathematically correct curve that would disclose, on inspection, the proper license fee to be charged any other truck on solid tires whose capacity and maximum speed were known.

In a similar way, the maximum license fee for trucks equipped with pneumatic tires could be determined and a similar curve plotted that would immediately disclose the proper license fee to be charged any other truck of that class.

The general proposition of having a roadway for trucks separate from the roadway used by pleasure traffic, constructed and maintained from the license fees to be paid on commercial trucks, is practical but it necessarily involves a considerable period of time to bring about, and what is necessary at the present time is immediate relief from the condition in which we find ourselves. The simple expedient is to increase commercial truck license fees, immediately widen most of the present main arteries of travel used by commercial trucks and, at the same time, commence the construction of parallel lines that will be devoted to the exclusive use of truck traffic and such limited, local pleasure traffic as may be necessary.

If it cannot be brought about that the federal government takes over the licensing, controlling and providing for commercial truck traffic, then by all means the various states should promptly determine, by appropriate joint action, a uniform and adequate system of license fees, maximum allowable weight, speed and size, together with an exactly uniform set of rules and regulations controlling all features of commercial truck traffic on public highways.

Commercial trucks which are devoted to strictly local traffic and not in direct competition with railroads should be licensed on a different basis from those which are engaged in long-distance hauling that is in direct competition.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Eccentric Heel Joint

Sir—Summarizing the discussion on heel joints of roof trusses in your issues of Aug. 30, p. 339; Sept. 13, p. 447, and Oct. 4, p. 568, it is worth pointing out that your correspondents, while differing in methods, are practically agreed on results.

Edward Godfrey's solution will furnish accurate values for flat roofs, and it may be committed to memory. However, it will give the direct stresses in reversed direction. This, too, has to be remembered. Formulas, when available, will give quicker results.

Attention should be called to a typographical error in Mr. Godfrey's sketch. The sum of the shears at C and T is $R(p - l)/p$ instead of $R(p - l)/l$. To be consistent, arrow heads at C , T and O should be opposite to that of R .

The assumption, $l_1/l_2 = l_1/l_2$, which Mr. Weiskopf suggests, is a simplification at the expense of accuracy; but in a given case the error lies within control of the engineer.

Bethlehem, Pa.,

Oct. 11, 1923.

CAMILLO WEISS,
Structural Engineer.

Slump Tests, Religion, and Drinking Water

Sir—Recently the Engineers' Society of Western Pennsylvania took a trip to Detroit and viewed some engineering work in that city. We were entertained by the Engineers' Society of Detroit, and the entertainment was all that could be desired. We had luncheon in one of the largest office buildings in the world and inspected the largest filter plant in the world.

One of the most impressive things we saw was that apparently non-dividend-producing thing called house-cleaning. It was evident in the plant where they squirt out the Fords, in the Detroit-Edison power plant, and in the water-works. Sweeping down the outside walls of a power plant, sweeping up the floors of a factory and a steel plant, painting with aluminum paint the bustle pipes of a blast furnace, to say nothing of burning coal economically and completely by using stokers outside, no doubt, of the smoke consuming zone; these things are worth while, but we could name localities where they do not mean anything, if we wanted to be disloyal.

It was only a few years ago that our leading doctors were telling us that it was useless to filter water, that a germ could squirm through any filter made, and that the only safe way is to boil the water 10 or 15 minutes.

Here is Detroit with a plant that is capable of converting 400,000,000 gal. of river or lake water into safe drinking water every day, and the proof of it is the great reduction in the death rate due to typhoid fever.

The church and its founder are often criticised because they have no social program, simply cleansing the fountain-head, the source of all evil and good, the individual heart, and these critics would, by mass psychology, correct the actions of men—boil the water at the faucet. This, of course, is religion, but even engineers can think and talk along religious lines if need be.

A thing that impressed me about the reinforced-concrete filter tanks is the fact that in large areas there is no provision for expansion and contraction other than the steel reinforcement. I asked about the method of waterproofing. No waterproofing—simply fluid concrete. Any leaks? No.

Investigators are making thousands of tests with the sole aim of discovering how to make concrete of the absolute maximum strength, and water content of the absolute minimum is all they can see. High compressive strength is of minor importance, and the attaining of it is very

uncertain, because it requires extreme care and expert supervision.

Density and impermeability and ability of the concrete to flow readily around the reinforcing steel are of the utmost importance, and these can only be attained by the use of fluid concrete.

Men everywhere are ridiculing and condemning the slump test, and with reason. I should like to ask any advocate of the slump test, and the stiff concrete that the application of any slump test implies must be used, what slump test he would recommend for the enormous girders illustrated in your issue of July 5, 1923, p. 7, where the tremendous volume of steel in the balcony girder of a theater in Los Angeles allows room for not much more volume of concrete than that of the steel. This is massive concrete. The latest Joint Committee Report gives a slump test of 2 for this character of construction. Is there an engineer living who imagines that concrete of such consistency could be worked around this steel or that concrete remotely approaching this consistency would be appropriate here?

EDWARD GODFREY.

Pittsburgh, Pa., Oct. 9, 1923.

In Defense of the Cement Companies

Sir—I have read with much interest the letter from O. T. Reece, county engineer, Neosho County, Kansas, which appeared in *Engineering News-Record*, Oct. 4, 1923, and in which he refers to certain methods of marketing cement.

The cement company with which I am connected has its plant in the Lehigh Valley. I have no knowledge of the marketing methods of the cement companies to which Mr. Reece refers, but inasmuch as his letter apparently assumes that the marketing methods to which he objects are those of all cement companies in the United States, let me call attention to the fact that in this section of the country the situation to which he refers has not arisen in our dealings with our customers.

As a matter of fact, we are selling cement direct to the state highway department of Connecticut and have signified to at least one other state governor our willingness to sell direct to that state. In one very recent case we offered to sell direct to the state highway department of Pennsylvania but in that state the purchases of cement are made direct by the contractors doing the work.

It is true that we have sold these contractors generally through dealers but we have found no objection on their part to this custom. Apparently the dealers in this section can, with a reasonable margin of profit, cover services which they perform for the contractor.

I have never heard of such sums as Mr. Reece mentions, "from 25 to 60c. per barrel," going to any local representative of our mill or any dealer handling our product. On the contrary, dealers in Pennsylvania through whom we have received contracts for state highway work have taken a profit of as low as one, two or three cents per barrel. In one case with which I am familiar, and in which they received as high as 10c. per barrel, we were unwilling ourselves to handle the account direct on account of a question in our own minds as to the credit rating of the contractor concern. Nor have I ever heard in this district of any such "margin" as Mr. Reece refers to "in one case 76 cents per barrel and in another 87 cents per barrel."

Of course, the principal reason for our selling the large percentage of our cement through dealers is that it is apparently the desire of our customers in this section to do business in that way.

Mr. Reece also refers to "association rules" in connection with the marketing methods to which he objects. The only association of cement companies that I know of is the Portland Cement Association which has nothing whatever to do with marketing methods or the price at which cement is sold. It is an organization devoted entirely to the promotion of the use of cement; to technical research; and to the assistance in the proper use of cement in highway and building construction.

JOSEPH BROSTON,

Vice-president, Dexter Portland Cement Co.

Nazareth, Pa.,

Oct. 22, 1923.

Critical Tests for Earth Dams, With or Without Cores

Sir—The recent failures of earth dams and the variety of causes assigned bring us squarely to a consideration of the action that takes place when an earth embankment is subjected to its initial saturation, or to a renewed hydrostatic pressure after being allowed to dry out for a long period.

Observations taken during the initial test of 200 miles of canals and laterals, and more than twenty earth-fill dams, constructed during different seasons of the year, and involving various amounts of moisture and compacting, on dams up to 120 ft. in height, and on fills for embankments ranging up to 50 ft., have defined some critical periods which may or may not recur for the same structure.

A loose earth dyke on being first subjected to hydrostatic pressure will rapidly become saturated on the water face, and for varying depths within the mass, dependent upon the porosity and degree of compactness. As the surface of the reservoir rises, the plane of saturation progresses upward, coinciding with the hydraulic gradients for the given material at the various elevations. The portions will become saturated and subjected to settlement in the numerical order shown by Fig. 1. Resulting from the subsidence of any given section there is a tendency for caverns of arched tunnels to form, inviting a free flow of water

FIG. 1—SUCCESSIVE PLANES OF SATURATION

farther into the interior of the embankment, until the degree of saturation and weakening of the cohesion causes a caving of additional material from the roof section. A critical period arrives for the dyke every time one of the tunnels or caverns retains its roof intact for a considerable period, allowing free access of water flowing to the interior, and tending to form a blister or lens of liquid under pressure near the downstream face. If a well compacted stratum is encountered, such as would result from highway traffic across the fill during a lull in the construction, the roof of the cavern or tunnel may endure until an accumulation of water or a channel has been so thoroughly established as to cause the certain and rapid failure of the dam. However, the agitation of the body of water due to the falling masses from the roof, causing a sort of surge and water hammer action, usually insures the continuance of the caving process and thus prevents the formation of a long tunnel or a cavern of great dimensions.

All earth dams that function must undergo a similar test at least once, the saturation and subsidence and forming of vaulted caverns differing only in degree from the extreme case above described. The dry fills confining the sluiced materials of hydraulic-fill dams are subjected to the test during construction; and it is safe to assume that all recurring ones will be less severe. Dams provided with a complete cutoff and corewall (Fig. 2) or with durable and effective sheetpiling cutoff surmounted by the impervious diaphragm and adequately connected with the canyon walls, undergo saturation for only the upstream section. The downstream portion, constituting at least 60 per cent of the structure, is nearly constant in volume, and unless actually overtopped by floods it will remain indefinitely. The presence of the corewall prevents the movement of currents of water in the saturated upstream portion, and hence prevents the loss of the soluble elements.

Failure of Apishapa Dam, Colorado—From the various accounts of the construction, behavior, and failure of the

Apishapa dam it appears evident that the initial saturation of the upper strata of this structure was attended by the formation of the tunnels and cavernous structures above described. No doubt this was accentuated by the loss of soluble materials. Mr. Mann's judgment concerning the probable settlement of 5 ft. after filling appears to be justified. If the roofs of the caverns and tunnels that caused the main leaks at Points A and B of the plan appearing in *Engineering News-Record*, Sept. 13, 1923, p. 419, could have been made to cave in and check the flow while the saturated material settled to its proper place to fill the sharp crevasses along the planes of cleavage, where the main fill evidently faulted due to its greater subsidence, it is quite probable that the structure would have remained intact. McMillan Dam on the Carlsbad Project, New Mexico ("United States Irrigation Works," by A. P. Davis), was saved under very similar conditions in 1914 by the prompt discovery of the well defined channel, and the temporary closure with sacks of earth.

The Avalon Dam, New Mexico—Prior to the adoption of the Carlsbad Project, New Mexico, by the U. S. Reclamation Service, the Avalon dam on the Pecos River had failed twice; the first time in 1893 by overtopping; the second time in 1904, probably from causes similar to those at the Apishapa dam and to the threatened failure of the McMillan dam above referred to. The U. S. Reclamation Service installed a combination of reinforced-concrete core-

FIG. 2—CROSS-SECTION OF EARTH DAM WITH COREWALL

wall and steel sheetpiling surmounted by a riveted steel diaphragm.

Quoting from Mr. Davis's treatise, referred to above: "The provision of a corewall was an innovation upon the usual Western practice, and especially that of the Reclamation Service. Its necessity arises from the presence of a large percentage of soluble salts in the earth available for the embankment. In use, the slow percolation of water through such a bank gradually leaches out the soluble matter, leaving the bank more and more porous, and it soon becomes unreliable as a barrier against water. The corewall is thus made necessary, and also serves the purpose of preventing destruction through the ravages of burrowing animals."

Failure of the Schaeffer Reservoir Dam, Colorado—The great flood at Pueblo, Colo., June 3 to 6, 1921, was prolonged at a destructive stage by the failure of the Schaeffer reservoir dam suddenly on June 5. The freeboard from the floor of spillway to the crest of the dam was 10 ft., and failure occurred with only a 4.5-ft. depth on the spillway. To an observer who witnessed the failure, the water appeared to give a great surge that overtopped the central 75-ft. section, and the reservoir was empty in about half an hour. It will remain a question whether the water surged over the central portion as a great wave, or whether subsidence of the saturated maximum section reduced the crest below the water level. Another question for speculation is the effect that a complete corewall or diaphragm would have produced, at both the Schaeffer and the Apishapa dams. It is probable that 5 per cent of the cost of an earth dam will provide a complete diaphragm or corewall, especially where the cutoff walls are already installed and the core construction keeps pace with the earth fill.

Modern engineering practice, wherever earth dams are extensively used, has tacitly recognized that percolation will take place through such structures unless stopped by

such positive means as a corewall or a diaphragm. An eminent engineer who failed to accept this fact very naturally condemned a large dam then under construction because of the coarseness and lack of cohesion of the downstream section. He built another dam conforming to his idea that the downstream portion should be just as impervious and cohesive as the upstream face; this dam failed, probably due to inadequate drainage of the percolating water; while the dam condemned by his judgment on account of its coarse pervious downstream section is listed among the successful earth structures, in standard engineering works.

Dry earth embankments have been built during emergency conditions with a double-lap plank diaphragm; and when subjected to hydrostatic pressure which caused marked settlement and consolidation of the upstream section, the timber diaphragm functioned perfectly and retained its original alignment very closely.

The writer has been unable to discover a single case on record where an earth dam with complete corewall or

essary before he reaches the track. If he cannot see without stopping he must stop."

It may be advisable to delegate to state public service commissions or similar bodies the power to post at blind crossings, notices requiring automobile drivers to stop their automobiles before making such crossings, but if thirteen million drivers in the United States should be required to come to a full stop every time that they make a crossing where an extended view of the track is available the greatest possible impetus would be given to the plan of separating at once all grade crossings.

More care should be exercised by state highway departments to eliminate grade crossings when practicable during the reconstruction of state highways. In one state two grade crossings at which there have been several deaths and two or three automobiles demolished could have been eliminated at a cost of but little more than the amount expended in improving the road connecting those crossings. A device which would save many lives would be to paint on the sign at a crossing the number of tracks at the crossing. People frequently see one train pass the crossing and, thinking it to be a single track and that there will be no more trains, run onto the crossing only to be struck by a train on another track.

It might be desirable also to empower a state public service commission after studying the conditions at a dangerous crossing to require the train to stop before proceeding over the crossing or to slow down so that it can stop to avert an accident providing that there are but few trains per day on the railroad at that point while there are many crossings per day by automobiles.

The whole endeavor should be to secure as much safety to the careful driver as practicable without enacting laws which needlessly impose burdensome restrictions upon him. The careless driver is hard to reach. In one state the law requiring all automobiles to come to a full stop before crossing a grade crossing seems to be about as effective as the non-tipping law. The constant effort should be to separate grade crossings as fast as is expedient.

More care should be exercised in the character of signs erected. On one state trunk line where the highway parallels the railroad and passes under the tracks by a right angle turn a large sign with circles like a target is erected with "STOP" painted in huge type. No one stops, it is not expected by those who erected the sign that anyone will stop. Thus the force of signs is weakened and the impression is created that the message on the sign need not be obeyed.

CHARLES A. HOLDEN,

Director, Thayer School of Civil Engineering,
Hanover, N. H.,
Sept. 20, 1923.

Elimination of Plants from Reservoirs

Sir—In the course of my weekly perusal of your journal I have noted a reference to the trouble of one of your Colorado correspondents caused by water lilies (*Engineering News-Record*, Sept. 27, 1923, p. 509), and I venture to offer the results of my observations on this subject in the Far East, as they might possibly indicate another way out of the difficulty. In central China, where there are vast areas of waterlogged land, the natives collect the roots of the water lilies and dry them out to make a kind of flour, as you suggest. This food is appreciated only by the poorest of the inhabitants, so it is, apparently, of no great value. It is, however, quite noteworthy that the collection only goes on in water where the men reaping the harvest can stand on the bottom with the water just up to their arm-pits—say less than 5 ft. The men feel about for the roots with their feet and when they are discovered tear them up, to be taken away by the attendant sampan (native boat). Now it is noticeable that the lilies grow abundantly in water of the depth just mentioned; in other depths they do not flourish. Might it not be possible, after allowing for climatic variations between Colorado and Hunan, to overcome your correspondent's trouble by either increasing or reducing the depth of water in which the lilies are growing?

London, England, Oct. 16, 1923.

"PHILIP"

FIG. 3.—HETCH HETCHY HYDRAULIC FILL DAM WITH COREWALL; UNDER CONSTRUCTION, OCT. 8, 1922

diaphragm has failed except through overtopping or a defective tunnel. It seems to be well established that the best insurance that can be provided against failure, either under the initial or the recurrent tests to which earth dams are subjected, is a complete cutoff and corewall or diaphragm from foundation to high-water level. The Hetch Hetchy Project for San Francisco's water supply includes a hydraulic-fill dam with corewall (Fig. 3) that represents the best practice for such construction.

Phoenix, Ariz., Sept. 27.

C. S. JARVIS,
Civil Engineer.

Highway Accidents at Railway Crossings

Sir—The abatement of automobile accidents at railroad grade crossings is a problem which deserves very intensive and extensive study by the greatest possible number of people. There is much need, however, that those who concern themselves with this problem should keep their judgment well balanced. They should realize that only a small percentage of automobile accidents occur at grade crossings, that proposed methods for their elimination should be such as to appeal to people as reasonable and sensible and that before enactment any proposed law should be tested in actual practice by representative automobile drivers from different parts of the state and under varying conditions. There is much need for uniform state automobile laws.

Some railroad executives and others propose as one method of prevention that all automobiles shall come to a full stop at all railroad grade crossings. A method which better appeals to the reason is contained in an opinion rendered by Justice Charles C. Van Kirk, of the Appellate Division of the Supreme Court of the state of New York. In this opinion Justice Van Kirk said, "The safe limit to speed in approaching a crossing is that speed at which the driver of an automobile, as he arrives at a point where he can see an on-coming train, when it is near enough to render crossing ahead dangerous, can stop his car if nec-

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

Highway Research Board to Hold Annual Meeting

National Research Council Body
Will Meet in Washington
November 8 and 9

The third annual meeting of the Advisory Board on Highway Research of the National Research Council is to be held at the headquarters of the Council in Washington, D. C., Nov. 8 and 9. The status of research in the various fields of highway engineering and transport will be evaluated as the basis for further research in this element of highway transportation.

Besides routine matters which include approval of interim actions of the executive committee, appointment of committee on nomination of officers, and the report of the director, there will be reports of various committees as follows:

Report of Committee No. 1, on economic theory of highway improvement, chairman, T. R. Agg, Iowa State College.

Report of Committee No. 2, on structural design of roads, chairman, A. T. Goldbeck, U. S. Bureau of Public Roads.

Report of Committee No. 3, on character and use of road materials, chairman, H. S. Mattimore, Pennsylvania State Highway Department.

The above reports will be made on the morning of the first day's session and in the afternoon an inspection tour will be made of the new building of the National Research Council and the experimental farm of the Bureau of Public Roads at Arlington, Va. The evening session of Nov. 8 will include an address by Thomas H. MacDonald, chief, Bureau of Public Roads; a report upon highway research work of the American Association of Land Grant Colleges, by Dean Anson Marston, of Iowa State College; a report of Committee No. 6 on highway finance, of which Dr. J. G. McKay, U. S. Bureau of Public Roads, is chairman; and an explanation of the research program of the North Carolina State Highway Commission by Charles M. Upham, its chief engineer.

During the third session, to be held the morning of Nov. 9, a report of Committee No. 4, on highway traffic analysis, of which George E. Hamlin, of the Connecticut Highway Commission, is chairman, will be made. Committee No. 7, on maintenance, chairman, W. H. Root, will also report.

Aldred Lectures at M.I.T.

Massachusetts Institute of Technology has announced that the first of the twelve lectures under the course of lectures established by J. E. Aldred will be held on the afternoon of Nov. 9. Gerard Swope, president of the General Electric Co., will deliver this first lecture. A number of prominent men representing all branches of industry will address the following meetings, which are scheduled to cover the next five years.

Charles P. Steinmetz Dies

Dr. Charles P. Steinmetz, consulting engineer for the General Electric Co. and world famous electrophysicist and inventor, died suddenly at his home in Schenectady, N. Y., Oct. 26.

He had returned but a week or two before his death from a tour of the Pacific Coast, and the exhaustion incident to the trip is presumed to have been indirectly responsible for his death.

Dr. Steinmetz came to the United States from Germany in 1889 at the age of 24, having been born in Breslau. He had received a thorough scientific training in his native city, in Berlin and in Zurich, Switzerland. His first employment in this country was with the Osterheld & Echemeyer Manufacturing Co., Yonkers, N. Y., first as draftsman, then as electrical engineer and designer, and finally on research work in charge of the laboratory. With the absorption of the Echemeyer interests by the General Electric Co. Dr. Steinmetz joined the latter organization, and for virtually the entire 30 years he was with that company, he was its chief consulting engineer.

Early in his career in America Dr. Steinmetz was made professor of electrical engineering at Union College. Later his title was changed to professor of electrophysics, and this chair he held until his death. He was granted an honorary Master of Arts degree by Harvard in 1902 and an honorary Doctor of Philosophy degree by Union the next year. He was a past president of both the American Institute of Electrical Engineers and of the Illuminating Engineering Society.

Dr. Steinmetz' 200-odd inventions were concerned largely with the transmission of power and the design of alternating current motors, though they also covered the magnetite-arc and other lamps, elevator motor appliances and electrically-propelled vehicles.

Coffin Medal Awarded

The Charles A. Coffin Gold Medal, created by the General Electric Co. for the best contribution to electric transportation, was awarded to the Chicago, North Shore & Milwaukee R.R. Co. at Atlantic City Oct. 11 at the annual convention of the American Electric Railway Association, the award being made on the basis of success in "giving service and telling the public its story."

Engineers See Coolidge on Federal Reorganization

Am. Soc. C. E. Committee Pleads for Unification of Non-Military Engineering Services

Washington Correspondence

President Coolidge evidenced great interest in securing the viewpoint of civil engineers concerning the question of government reorganization, particularly that having to do with public works, when Charles F. Loweth, president of the American Society of Civil Engineers, together with a special committee from that society, waited upon him Oct. 30 to present and explain a resolution adopted by the Board of Direction of the society. The President asked numerous questions and apparently was impressed by statements of the members of the committee that the creation of a Department of Public Works alone constitutes a plan of the greatest value in making possible numerous efficiencies in the conduct of the engineering and technical services of the federal government.

The President was assured of the civil engineers' interest as citizens in the general plan of reorganization. They pointed out, however, that members of their profession probably are qualified to advise most intelligently concerning that portion of the plan which affects reorganization of the Department of the Interior. The President expressed his appreciation of the tender by the engineers of any assistance, either to him or to his assistants, they could render in the development of the plan.

LETTER GIVEN COOLIDGE

The letter which the special committee handed to President Coolidge follows:

"As members of a committee appointed by the Board of Direction of the American Society of Civil Engineers, we come to present to you resolutions adopted by said Board endorsing and commending the recommendations of President Harding and his cabinet for the reorganization of the executive departments of the government, and more particularly those having to do with public works.

"For many years the engineers of this country have been keenly interested in the activities of the government in the field of public works. As a result of conditions developed during the war period an intensive study of governmental methods of administering public works was made by them.

"This and other efforts culminated in S. B. 2232 to create a Department of Public Works and define its powers and duties; and in bills before the House, H. J. Res. 339 and 390, to create a Joint Committee on the Reorganization of the Administrative Branch of the Government.

"Later, the engineers of the country were gratified by the recommendations of the President which were based upon

a careful study by the Joint Committee on the Reorganization of Government Departments authorized by the last-mentioned bill.

"The American Society of Civil Engineers is the oldest of the national engineering societies in this country. It has a membership of 11,000 from all parts of the country. Many of its members are thoroughly experienced in the administration of public works and affairs.

"This society bespeaks your active interest in this measure, particularly with respect to the provisions relating to the administration of public works, to the end that it may become law. The resolutions passed by its Board of Direction are attached hereto.

"The Board will be happy to be of service to you in this connection.

"Yours respectfully

"C. P. LOWETH, President
and Chairman of Committee, Chicago

"WILLARD T. CHEVALIER

New York City

"A. H. MARKWART

San Francisco, Calif.

"LEONARD METCALF

Boston, Mass.

"CHARLES H. PAUL

Dayton, Ohio."

The resolution passed by the Board of Direction reads:

"RESOLVED: That the Board of Direction of the American Society of Civil Engineers endorses and commends the recommendations of the President of the United States and his cabinet, that the military and non-military engineering activities of the government be separated and that the design, construction and maintenance of non-military public works be assembled as far as practicable in one department, under one head, and that only those activities closely related thereto be included in that department. We also commend the effort to apply similar principles to all the departments, and to allocate the numerous independent offices to appropriate departments so far as possible. We believe such action will tend to eliminate duplication, to co-ordinate public activities, and in many ways to promote economy and efficiency in the public service.

"RESOLVED, That the president of this society be empowered to appoint a committee of five members of this society of which he shall be chairman, to present the above resolution to the President of the United States, and to appropriate officials of Congress, and to the executive departments, and to take such other action as it deems wise in furtherance of the principles above endorsed."

Highway Conference to Be Held at Michigan University

The tenth annual Michigan conference on highway engineering will be held Feb. 11-14 at Ann Arbor. The list of speakers will include engineers from the Michigan State Highway Department, county commissioners and engineers, municipal engineers, members of the faculty and prominent highway engineers from other states. The conference will be open to all highway commissioners, engineers, contractors and others interested in highway improvement. No fees will be charged by the University. The program will be issued in January, 1924.

Pueblo Soon to Receive Bids on Flood-Protection Work

Plans for flood-protection work in Pueblo, Colo., have progressed to such an extent that bids will be received within the next two months, according to advices from the Dayton Morgan Engineering Co., in charge of engineering. Work will involve the construction of a new channel for the Arkansas River through the city which shall carry 125,000 sec.-ft. of water; and building 34 miles of railroad track and a barrier dam 35 ft. high and 3,060 ft. long. The plan has been officially approved and benefits appraised upon which assessments will be levied. The total estimated cost of the project, including land and administration, is \$4,000,000. The project was described in *Engineering News-Record* July 12, p. 48. Formal approval was given the plan by District Judge Park early in August. (*Engineering News-Record* Aug. 16, p. 280.)

New Bridge for Springfield

The city council of Springfield, Mass., has authorized the construction of a permanent bridge across the Connecticut River at a cost not to exceed \$1,000,000, to replace the one destroyed by fire in September (*Engineering News-Record* Sept. 13, p. 449, Sept. 20 p. 488). The bridge is to be built jointly by the city of Springfield and the town of West Springfield, the first-named paying nine-tenths of the cost and the last-named one-tenth. Dr. J. A. L. Waddell, New York, has been chosen by the joint committee to prepare plans for a bridge, in which work he will not be restricted to any particular type and will submit plans for both steel and concrete structures. There has been no hard and fast decision as to cost, this being governed in a large degree by the material decided upon. On financial grounds a steel bridge is favored, but on the other hand there is considerable sentiment in favor of a structure that promises to be most durable, even though it shall cost more. Speed in the completion is also regarded as an important consideration. A tentative plan has been presented for a nine-span steel open-deck bridge, 1,126 ft. long and 66 ft. wide.

Los Angeles Considers Colorado River Water Supply

Acting under instructions from the Board of Public Service Commissioners William Mulholland, chief engineer of the Los Angeles Bureau of Water Works and Supply, has put surveying parties in the field to determine the feasibility of bringing water from the Colorado River to supplement the city's existing water supply. Mr. Mulholland, who suggested the possibility of a Colorado River source after a recent inspection trip, stated in reply to an inquiry from a member of the *Engineering News-Record* staff: "At the present per capita rate of consumption the city's water supply from Owens River sources is sufficient for 2,000,000 people but an influx of manufacturing enterprises may change that rate." The city has not yet obtained a government grant to divert Colorado River water.

Reclamation Conference for New Orleans

Forestry and Home-Making Topics
Also Scheduled for Meeting
Nov. 19-22

A conference on forestry, reclamation, and home making is to be held at the Hotel Grunewald, New Orleans, Nov. 19-22, under the auspices of the Southern Pine Association, the Florida Development Board, the Mississippi Development Board, and the New Orleans Association of Commerce. An exceptionally interesting program has been prepared with the discussion headed by the following principal topics:

Use of waste lands for creation as needed of opportunities for rural homes; best means for utilizing denuded and cut-over lands through reforestation, grazing and agriculture; a national and state policy for handling and taxing such lands; forestry problems—a systematic plan for better use of the forest resources of the country and for insuring a permanent and adequate timber supply for the nation; subsidizing settlers on reclaimed lands—need of aid furnished by national and state agencies to encourage permanent and prosperous settlement; revision of existing reclamation law to make it nationally applicable, instead of sectionally as at present, thus more effectively meeting the needs of the country in creating opportunities for homes; settlement methods—successful ways of securing and safeguarding desirable settlers who may utilize the lands now idle; grazing and development of the animal industry; selective immigration; and financing the rural home-maker.

RESOLUTIONS TO BE OFFERED

A series of resolutions has been prepared for discussion and possible adoption. Among the most interesting of these is the following:

"Resolved, that we request the Congress of the United States to consider the recasting of the entire reclamation law, making it applicable to all parts of the United States, eliminating conditions which make speculation easy and which have encouraged tenantry and promoted soil deterioration, at the same time extending the good features of the law so as to be applicable to the reclamation and best use of lands in whatever part of the country they may exist. Such development to take place at the time and in the manner to best promote the creation of opportunity for self-supporting farm homes. Also, that the organization of a reclamation service be provided for by law and be placed on a permanent basis. The reclamation act should be recast to provide a well considered bureau of service under a director or other officer selected for experience and ability, appointed by the President with the advice and consent of the Senate, and removable only for cause."

The executive committee has for its chairman C. S. Ucker, of Baltimore, Md. The headquarters of the conference are at 616 Real Estate Bank Building, New Orleans, La., or 904 International Building, Washington, D. C. The exact title is the Forestry, Reclamation, and Home-Making Conference.

Founder Societies Move Toward Co-operation

Joint Committee Agrees on Conference
Committee Consisting of Pres-
idents and Secretaries

A move toward more active co-operation of the four national engineering societies was made on Oct. 29 when a joint committee of the societies adopted a report recommending the formation of a Joint Conference of the four Founder Societies with a membership consisting of the presidents and secretaries of the societies. The report will be submitted to the governing bodies of the societies as soon as possible and when accepted by each will be put into force. It was adopted Oct. 29 by the Council of the Mechanical Engineers.

In anticipation that this report will be adopted by the other three Founder societies a meeting of the Joint Conference Committee has been called for Dec. 10 at the Engineering Societies Building, New York, to consider any business that may be brought before it and particularly to consider the possible enlargement of the activities of Engineering Foundation.

The report reads as follows:

"At the meeting April 16, 1923, of the Board of Direction of the American Society of Civil Engineers the appointment of a committee of five, the chairman to be the President, was authorized to confer with the officials of other national engineering societies with a view to formulating some permanent, workable method of joint co-operation on public matters and report its recommendations to the Board. Invitations to appoint members of such a joint committee on co-operation were promptly accepted by the three other Founder Societies. At the first meeting of the joint committee July 24, 1923, a thorough discussion of co-operation was participated in by all sixteen members present. As a result a subcommittee, consisting of the presidents and the secretaries of the four Founder Societies, was authorized to report at the next meeting of the joint committee on two matters, as follows:

"1. The possible fields and means of joint co-operation of the four Founder Societies.

"2. Possible modifications in the Federated American Engineering Societies.

MEANS OF CO-OPERATION

"With reference to the first matter, your committee has given careful consideration to the possible fields and means of joint co-operation of the four Founder Societies. There are many activities on which the four Founder Societies have been co-operating for many years, and in regard to which they should continue to confer in order to exchange information, determine policies, and secure concert of effort in the execution of these policies. The following lists of such activities are submitted as representative only, and are not intended to be inclusive or exhaustive. It is recognized that the activities listed fall into two general classes; first, those which concern both the four Founder Societies and the whole engineering profession; and second, those which concern only the four Founder Societies. In the arrangement of the lists, no importance

whatever should be attached to the order in which the activities are given.

Activities Which Concern Both the Four Founder Societies and the Whole Engineering Profession

1. Engineering education.
2. Professional ethics.
3. National and state legislation of interest both to the public and to the engineering profession.
4. Registration of engineers.
5. Co-operation with other organizations.
6. Preservation of efficiency in public offices requiring engineering knowledge, as exemplified by the office of Director of the United States Reclamation Service.
7. Local Sections. While at first thought it may appear that local sections are the concern of only the four Founder Societies, yet it should be remembered that the American Society of Automotive Engineers and several other societies have their local sections, and that furthermore, the activities of these local sections are closely related to the activities of many local and regional engineering clubs.
8. The Engineering Employment Service. While this service is at present restricted to the members of the four Founder Societies, it is anticipated that there is some possibility of the scope of the service being widened in the future.
9. Research.
10. Standardization.
11. Publicity.
12. Engineering abstracts and indexes.
13. International engineering congresses.
14. International relations.

- (a) Foreign relations.
- (b) The exchange of courtesies as in the case of exchange professors to the United States from foreign countries.
- (c) The Kelvin Medal.
- (d) Pan-American relations, such as those in the field of standardization.

Activities Which Concern Only the Four Founder Societies

15. Administration of the joint property by the United Engineering Society.
16. The Engineering Societies Library.
17. Engineering Foundation.
18. Joint professional meetings.
19. Arrangement of the yearly schedule of time and place for regional meetings and conventions.
20. The award of the John Fritz Medal.
21. Student branches.
22. The technical and professional divisions and committees of the four Founder Societies.
23. Joint committees, including both the technical committees and the non-technical committees, such as the Joint Finance Committee.

"In view of these and similar inter-society activities it is recommended that the policy of co-operation followed for many years past by the four Founder Societies be fostered in the future. As

Philadelphia Engineers Hear Talk on Japanese Earthquake

Interesting sidelights on the Japanese earthquake were presented before the Engineers' Club of Philadelphia on Oct. 23, by Dr. Judson Daland, who recently arrived home from Japan. Dr. Daland was in Tokyo on Sept. 1 when the earthquake occurred going from Tokyo to Kobe afterward.

Recovery from the earthquake, according to Dr. Daland, has been hampered by three things: first, a general hysteria that seized the people, and that roused up race hatred with the Koreans; second, a dazed condition of people in which they seemed unable to start about reconstruction work; and third, the action of the Japanese government in refusing to give information about the disaster.

In Tokyo, Dr. Daland said that no production had been started as long as six or seven days after the earthquake. The Japanese government has been persistent, he asserted, in withholding information about the extent of the disaster.

to the machinery necessary to bring about the proper co-ordination of effort of two or more of the societies, it is believed that at the outset a Joint Conference Committee consisting of the four presidents and the four secretaries would be an effective means of giving preliminary consideration to the various problems, of suggesting the policy to be followed in each case and of recommending the procedure for carrying out these policies, using as far as practicable existing agencies. The first chairman of the committee, for a term of one year, should be the president of the American Society of Civil Engineers, and thereafter the president of each of the four Founder Societies in order of seniority. Whenever a president or a secretary cannot attend a meeting of the committee he should appoint an alternate.

"In regard to the second matter upon which the subcommittee was asked to report, namely, possible modifications of the Federated American Engineering Societies, your subcommittee feels, since the representatives of some of the societies who are not, or may not be, members of the Federation might not wish to be placed in the position of recommending changes, that consideration of this phase of the problem should be postponed, particularly as a committee of the Federated American Engineering Societies is now considering this very thing.

Respectfully submitted,

What's Ahead in Business, as Judge Gary Sees It

Extracts From Address of Steel Head at Iron and Steel Institute Meeting in New York

"It is doubtful if our government can at present be of much assistance in attempts to restore the equilibrium of Europe. Voluntary advice or sympathy just now would not be acceptable. Practically, we can be of benefit only by example.

"It would not be appropriate for us to take sides in European controversies nor to condemn individual attitudes or conduct; but we know the great seas are not wide enough to separate us from the influences of disaster in Europe. We are affected in our finances, our commerce, our industries, our civic, political and social life and our morals. Citizens of Europe are embarking for the United States whenever possible; not always the most worthy are included, which is a pity. Their ideas permeate our social and business life. The whole structure of civilization has been shaken.

AN INDEPENDENT NATION

"If the European atmosphere and conditions dominated our affairs, our business men might be depressed and somewhat doubtful of the future; but fortunately they do not. We are, or at least we may be, independent of all other countries so far as business progress and prosperity are concerned. If we properly conserve and utilize our natural resources and legitimately manage our private and public affairs, availing ourselves of the opportunities that are presented, we may and will continuously and adequately prosper.

"There will be temporary interruptions, recessions, and there will be fluctuations, but the man of business courage, with a reasonably clear vision of the long future, pays little attention to temporary hesitation in business progress. He knows that the current of prosperity in the United States is so strong that even though it may be occasionally modified by unnatural or unreasonable obstructions, this will result in accumulation of volume and force which will soon be overwhelming and stronger than ever before.

"What is the disposition of the President concerning the affairs of the country? This is shown by a statement recently made by one occupying a prominent official position as follows: 'It is very evidently the aim and effort of the administration to encourage in every way policies in both business and politics which will tend to the elimination of agitation. The very evident desire in all governmental quarters is to extend the fullest assistance to the constructive forces of the country. The removal of elements of uncertainty and of misgivings, and the stabilization of business conditions, are a constant aim, and the feeling among those most familiar with the reflections of the business situation is that substantial progress is being made along these lines.'

"It is also important to know the opinion of the Administration concerning the present trend of business. This likewise was referred to by the same authority already mentioned, as follows: 'The impression in Washington seems to be that industry throughout the country is proceeding on a com-

Deeper Hudson Advocated

Special Correspondence

During the past three weeks there has been a revival of the boom for a deeper Hudson staged principally through the Albany newspapers.

This revival is said to emanate from those who want the Hudson dredged to a 27-ft. channel to Albany and eventually the Barge Canal deepened into a ship canal as an offset to Canadian projects.

The cities in the Capitol district have gone so far as to get together and form a committee; also to engage the Technical Advisory Corp., of New York City, to collate data regarding shipments of freight through Albany which is to be presented to the War Department and later to Congress with a request for an appropriation.

The dream of Albany is to become a seaport and bills will probably be introduced in the next legislature providing for a state appropriation for terminals and a law providing for a Greater Albany Port Authority.

There are those in Albany who cannot take the project seriously. They say that after the expenditure of forty or fifty millions boats 700 ft. long will come up to Albany direct from Liverpool and readily turn around in a 250-ft. channel. In the winter time the Hudson River will be heated with electricity generated in the St. Lawrence River so as to keep navigation open. Albany will become a seaport town with a population of 5,000,000; water front saloons with 5-cent whiskey and 3-cent beer will be established and New York City will be just a port of call. When help is scarce it will not be infrequent to see ocean going steamers go up onto Capitol Hill and shanghai a crew out of politicians.

Ohio Highways and Public Works Personnel Announced

L. A. Boulay, the new Ohio Director of Highways and Public Works, announces appointments, for the eleven divisions, of division engineers and assistant engineers, respectfully, as follows: Division 1, F. A. Daum and R. W. Fry; Division 2, M. I. Henahan and F. R. Bell; Division 3, T. S. Brindle and E. R. Graham; Division 4, F. E. Swineford and Q. A. Campbell; Division 5, W. G. Smith and C. B. Shaw; Division 6, R. S. Beightler and F. C. Higley; Division 7, H. C. Miller and G. D. Scheueman; Division 8, H. A. Nunlist and H. W. Walsh; Division 9, J. W. Graham and R. Z. Myers; Division 10, G. E. Carr and O. W. Merrell; Division 11, W. C. Fawcett and H. R. McCoy.

mentably conservative basis, with avoidance, so far as possible, of unnecessary advances in prices, or avoidable expansions which would engender keen competition for labor. With a continuance of this general attitude, it is felt that business should continue generally good for the remainder of this year. While there is reticence about making prophecies for the future, the general opinion seems to be that if this attitude continues there can be reasonable assurance of a projection of generally satisfactory business conditions at least well into next year. It is believed these statements represent the mind of President Coolidge.

Random Lines

On a Certain Condescension

He wore rather conspicuously the blue shield of the American Society of Civil Engineers and dangling from his watch chain was the gold badge of Tau Beta Pi. Quite obviously he had been trained and had worked as a civil engineer. But when some simple engineering question came up he smiled a deprecating smile and said, more proudly than otherwise, "Oh! I don't know anything about that. You know I'm in the selling end; I don't keep up on these engineering details." It wasn't the words that riled us; it was the condescending manner, the obvious superiority of one who had finally gotten out of the rut onto the broad highway of success. And we went away wondering how much of the engineer's complaint about his "status" was due to this all too common attitude of mind of the engineer himself. The world takes us at our own estimation—to a large extent, at least. If the engineer, taking him by and large, thinks he is rising in the world when he commences to sell things it will be a long time before the world stops paying him—and other salesmen—more money for selling things than for planning them and making them.

- FEDERATED AMERICAN ENGINEERING SOCIETIES, Washington, D. C.; Annual Meeting, Washington, Jan. 10-11, 1924.
- AMERICAN SOCIETY OF CIVIL ENGINEERS, New York City; Annual Meeting, New York, Jan. 16, 17.
- AMERICAN CONCRETE INSTITUTE, Detroit, Mich.; Annual Meeting (26th anniversary), Chicago, Ill., Feb. 25-28, 1924.
- ASSOCIATED GENERAL CONTRACTORS OF AMERICA, Washington, D. C.; Annual Meeting, Chicago, Ill., Jan. 21-23, 1924.

The Engineers' Club of Cincinnati had for its joint meeting with the Cincinnati chapter of the American Institute of Architects, on Oct. 18, a paper on "New Aspects of the Housing Problem" by Blecker Marquette, executive secretary of the Cincinnati Better Housing League.

The Illinois Municipal League will hold its annual meeting at Urbana, Ill., Nov. 1 to 3. The subjects of papers and addresses include the following: (1) Uniform traffic regulations; (2) inspection and purchasing methods for municipalities; (3) street resurfacing methods in Illinois; (4) publicity methods by which officials can keep citizens informed as to municipal activities; (5) city planning and zoning; (6) superhydro-electric power and its relation to municipal development. Prof. R. M. Story has resigned as secretary but continues as treasurer. The executive board, therefore, has appointed A. D. McLarty as full-time secretary in view of the growing activities of the league. His office is at Urbana, Ill.

Personal Notes

BARRY DIBBLE, project manager, U. S. Reclamation Service, in charge of the Minidoka Project and the American Falls, Idaho, development, has been transferred to the Denver office of the U. S. Reclamation Service to take charge of electrical and mechanical work, succeeding J. M. GAYLORD, electrical engineer, who has resigned.

FRANK A. BANKS, construction engineer, Minidoka Project, U. S. Reclamation Service, has been placed in full charge of the American Falls, Idaho, development hitherto handled by Barry Dibble; and DANA TEMPLIN, engineer on the Minidoka Project, has been made acting project manager.

ARTHUR T. LUCE, superintendent of the water plant, Des Moines, Iowa, has resigned to accept the management of the municipal water plant at Marshalltown, Iowa, Mr. Hazelwood, Mr. Luce's former assistant, is acting superintendent of the Des Moines plant.

M. F. DE WITT, who has been assistant city engineer of Tucson, Ariz., for the past three years, has resigned to become construction engineer and superintendent for Kelsey and Robinson who have a \$250,000 contract with the Mexican government for paving and a sewer and water system for Hermosillo, capital of the state of Sonora, Mexico.

FRANK H. KINSEY, formerly structural engineer in the construction department of the Bethlehem Steel Co., at Bethlehem, Pa., and chief engineer of the Edwin Burhorn Co., New York City, has opened an office as consulting structural engineer at 122 Bigelow Street, Newark, N. J.

CHARLES P. TOLMAN, after sixteen years as chief engineer and chairman of the manufacturing committee of the National Lead Co., has resigned and has opened an office at 111 Broadway, New York City, for consulting practice in manufacturing methods, handling materials and products, and dust and fume control.

WALTER G. KIRKPATRICK, of Atlanta, Ga., has accepted the professorship in municipal engineering at the University of Mississippi, succeeding Prof. Donald E. McLeod, who goes into engineering practice in North Carolina.

DAVID R. COOPER has resigned from the Fargo Engineering Co., Jackson, Mich., and has opened an office in the Dillaye Bldg., Syracuse, N. Y., for practice in hydraulic engineering, especially in the design of hydro-electric power plants.

PERCY A. CUPPER, state engineer of Oregon from 1918 to 1923 and attorney-at-law and consulting engineer, and ROBERT J. SIMPSON, assistant state engineer for the same period, announce the opening of a law and engineering office in the Oregon Bldg., Salem, Ore., and will specialize in water rights and cases involving operation and management of irrigation and drainage districts, water power, municipal works, and in general consulting engineering.

GEORGE LE BOUTILLIER, vice-president of the Long Island Railroad Co., has been elected president of the company to succeed the late Ralph Peters. Mr. Le Boutillier was born in 1876, graduated from the University of Cincinnati and in 1895 entered the service of the Pennsylvania R.R. in its engineering department. He remained in the engineering department, first as an assistant division engineer and then as a division engineer, until 1914, when he was transferred to the operating department as a superintendent. In 1920 he was promoted to be general superintendent at Harrisburg, Pa., and early this year he was elected vice-president of the Long Island R.R. to relieve Mr. Peters of the active management of the property.

IRA T. HOOK announces the opening of an office at 494 Norton St., New Haven, Conn., for industrial engineering service relative to materials and equipment, specifications, investigations, lay-outs, valuations and estimates. Mr.

Hook is a graduate of the University of Michigan, was formerly on the engineering staff of the General Motors Corp., and recently was assistant professor of strength of materials in Yale University.

W. H. ROGERS, JR., Greenville, N. C., has been appointed county engineer of Pitt County, North Carolina, succeeding J. B. Harding who died Oct. 3.

JAMES F. MUIR, formerly supervising mechanical engineer with Toltz, King & Day, Inc., of St. Paul, Minn., and prior to that superintendent of mechanical equipment for the Minnesota & Ontario Paper Co. at International Falls, Minn., is now engineer in the mechanical division in the Boston office of Stone & Webster, Inc.

R. D. CORRIVEAU, engineer, who has been with the Canadian Department of Public Works since 1898, has been appointed assistant chief engineer of the department, succeeding Kenneth M. Cameron, chief engineer.

A. J. MCCUNE, state engineer for Colorado from 1899 until 1903, and from 1917 until now, has resigned and retired from active work. His successor has not been named.

Obituary

VICTOR H. REINEKING, consulting hydraulic engineer, Portland, Ore., died Oct. 16 in Milwaukee, at the age of 38. Mr. Reineking graduated from the University of Wisconsin in 1908. He was resident engineer on the Kilbourn, Wis., project, the High Falls and Johnson Falls dams on the Peshtigo River and a municipal lighting plant at Decatur, Ill. In 1913 he entered private practice in Portland and in conjunction with L. F. Harza reported on the Celilo Falls project on the Columbia River for the State of Oregon. Other hydraulic and hydro-electric work was reconstruction of the Elwha River dam and power plant at Port Angeles, Wash., and the Ochoco hydraulic fill dam. For several years he was assistant engineer to Baar & Cunningham, consulting engineers, Portland.

W. H. O. MURRAY, railway contractor of Montreal, was accidentally killed at Fabre, Que., recently. Mr. Murray was engaged upon an extension for the Canadian Pacific Ry. in the Temiskaming District. He served overseas four years with the Canadian Railway Construction Corps as major.

HOLMES BLAIR, president of the engineering firm of Blair & Drane, Charlotte, N. C., died Oct. 25 at the Charlotte sanitarium after a long illness; he was 63 years old. Mr. Blair's early years were spent in railroad construction in Illinois, Montana, the Dakotas and Colorado.

J. B. HARDING, for the last four years county engineer of Pitt county, North Carolina, died suddenly Oct. 13, 1923, from a stroke of apoplexy at the loading plant of his paving project. He formerly served seven years as locating and reconnaissance engineer for the National Railway Lines of Mexico, and was also chief engineer for the Atlantic Coast Realty Co. of Petersburg, Va.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Interviews with Industrial Executives—I

Rock Drill Users Profit by Manufacturers' Policy of Field Service

WHAT is the manufacturer's responsibility to the purchaser of his equipment? Do his obligations end with the delivery of the product in good condition to the prospective user? Does the operation of the machine on the job concern him, or is the user the man upon whose shoulders the entire onus of operation and maintenance should rest? If not, what division of responsibility or what plan of co-operative service is possible and how can it be carried out in actual practice?

These are some of the questions to which equipment manufacturers have devoted a good deal of thought. No reputable maker would think of shipping to a customer a machine which was improperly designed, faulty in the character of its materials, or clearly unsuited to the work which it would be called upon to perform. Of course, scattered sales could occasionally be made by resorting to such practices, but the manufacturer seeking to establish or maintain his business on a stable, continuing, and expanding basis realizes that one of his biggest assets is the satisfied customer. In other words, the machine must not merely be right when it arrives on the job, but it must stay right, performing, day in and day out, its allotted task.

FOR EFFICIENT PERFORMANCE

The principle just enunciated is, in effect, the backbone of a policy of field service which the Ingersoll-Rand Co., manufacturer of rock drills and pneumatic machinery, has put into effect for the benefit of users of its equipment. It is realized that the successful and efficient performance of any piece of construction equipment must, in the last analysis, depend upon how it is treated by the man who runs it. In the case of rock drills, for example, the operator must be taught something of the structural limitations of his machine and be made to understand that he cannot ignore certain rules and then expect the tool to do its best.

Recognizing great possibilities, both for the maker and the user of equipment, in an educational service which would insure proper operation and maintenance on the job, the company has built up a corps of mine and tunnel equipment specialists who devote their entire time to visiting one job after another, inspecting machines and methods as actually employed on the ground, and, where faults are discovered, suggesting corrective measures. The following notes on the organization and operation of this field service force are based on an interview by *Engineering News-Record's* representative with J. H. Jowett, vice-president, and other officials of the Ingersoll-Rand Co. The organization's creed was expressed

Obligation of Maker Held To Continue After Sale of Machine—Corps of Skilled Advisers Visits Jobs To Improve Operation and Care of Equipment.

tersely by Mr. Jowett in these words: "The interest of this company has not ceased with the selling of its apparatus—it is equally concerned with its subsequent performance."

The company has headquarters in New York City and branch offices in 65 other cities, covering not only the United States, Mexico and Canada but Europe, Australia, Africa, South America, Asia, and the East. To the more

WALL CHART OF APPROVED PRACTICE

important branch offices one or more field service men are assigned. Their duty is to follow carefully what the tools are doing in the hands of their purchasers, and as a check on their activities some of the company's executive officers and technical experts make periodic surveys involving extended tours which enable local situations to be studied at first hand.

For the field service force only men with special qualifications are chosen. Obviously, they must have a background of practical experience in tunnels, mines, quarries and rock work generally. They must also possess a

thorough knowledge of the design, construction, and the use of the equipment which it is their duty to inspect, and, finally, they must be temperamentally equipped for the work, which calls for tact and the ability to win the confidence of the men on the job with whom they deal. They must not be averse to travel, as their duties require them to be constantly on the move from one job to another. Their sense of observation must be developed to a high degree so that both the large and small mistakes in operating methods or equipment use may be noted and corrected. A type of man must be selected for this service who can talk to chief engineers, superintendents, or bosses of tunnel shifts in their own language, calling for an experience in which theoretical and practical knowledge of methods and tools are blended.

Recently Mr. Jowett and other members of the Ingersoll-Rand organization made an extended trip through the Western states to survey the work of the field service force. They found on every hand evidence of the educational campaign which their field representatives were conducting for improving the service of drills and other machinery. The following notes cover some of the suggestions which the manufacturer, through his field service men, is offering to equipment users:

PRACTICAL SUGGESTIONS ON DRILL USE

Regular Inspection.—For the efficient operation of the rock drill the principle of the "stitch in time" is vital. Drill users are urged by the manufacturer to carry their machines back from the heading to some convenient point underground at the end of every shift, so that the tools can be examined, overhauled, cleaned, and oiled for service on the next shift. By following this practice minor repairs and adjustments can be made and the drill kept in service for long periods without having any serious accident occur. The expense involved, the manufacturer points out, is trifling compared with that entailed when drills must be taken all the way up to the surface and there turned over to the repair shops. In other words, frequent inspection underground offsets a rather common tendency on the part of the drill-runner to carry on with a defective or limping tool until the machine is put out of commission because of a really serious breakdown.

Lubrication.—One of the most important operating points stressed by the field service men is frequent and proper lubrication of rock drills. While the construction of the modern rock drill is extremely rugged, the service it is called upon to perform involves a great amount of wear and tear on the moving parts of the machine. Sometimes a service man encounters the spectacle of an operator endeavoring to loosen up a stuck drill with a flow of profanity and a sledge hammer. These are the men to whom the message of frequent lubrication must be carried. The remedy will often be found in the formula: "Feed the machine a little grease at a time, but often. When in trouble, lubricate!" Experience has shown that in most of the cases when steel is stuck the filling of the back and front oil pockets and opening up the throttle will free the steel.

It has been found by experiments covering a long term of years that "liquid grease" is especially suited to

the needs of rock drills. The company has made a careful study of lubricants and furnishes to purchasers of its equipment a list of approved greases and oils, which is printed on tags attached to the lubricating pockets of each machine when shipped from the factory. These printed instructions are followed up in the field by the company's service men.

The Scrap Box—One of the first points of inspection by the service men arriving on a new job is the scrap box. Here valuable information is usually secured. In the manufacture of rock drills standardization is carried to great

service men consists in impressing on the user the importance, first, of selecting drill steels of the proper quality and then outlying, for the benefit of the blacksmith on the job, the best methods or equipment for sharpening and tempering bits and forming shanks. By reason of its long experience in rock drilling, the company is in a position to suggest the most effective procedure, so far as equipment goes, in tunneling and mining operations, so that by following the hints of the field service men there is no reason for wasting time on cut-and-try methods. Often a suggestion regarding the type of bit best adapted

will and prolonging its life. It is not enough for the bits to be properly sharpened. One of the big sources of trouble lies in steels with improperly formed shanks. Defective shanks have been found to be the most common cause of piston breakage. Among the principal causes of trouble are shanks with ends not squared off true or with diameters too small to insure a snug fit in the rotation sleeve or chuck. In either case the piston strikes on the edge of the shank end, instead of distributing the full force of the blow over the entire area of the shank. The same effect is produced by a worn front chuck bush-

"THE WORK IN THE HEADING MUST BE CLOSELY CO-ORDINATED WITH THAT IN THE BLACKSMITH SHOP"

lengths and component parts are all made interchangeable. Sound drill parts are sometimes scrapped when they still have much working life left in them. This is, of course, due to a lack of knowledge on the part of the repair man. The service men emphasize the importance of much care in the repair of machines and show the repair man how to determine when parts are worn out. Frequently 20 per cent saving in tool upkeep cost has been made in this way. Mr. Jowett emphasized the company's appreciation of the helpful and constructive suggestions made from time to time by drill fitters, i.e., the men in charge of rock drill repairs, who from their every-day contact with repair problems often suggest simple modifications in design or construction which help to reduce the cost of maintenance.

Repair Part Stocks—In addition to their advice regarding the salvage and re-use of discarded parts, the service men aid drill users in determining the proper size and character of their repair part stocks. Owners of drills sometimes make the mistake of either understocking or overstocking with repair parts. The carrying of large quantities of reserve equipment involves considerable overhead expense, insurance, and the cost of maintaining storage facilities. Recognizing these conditions, the Ingersoll-Rand Co. has devised a system by which it carries a proper supply of repair parts at its main plant and outlying branches. Such stocks are kept up in accordance with an intimate knowledge of the changing needs of each customer. Under the plan the customer can be supplied at short notice and he need not carry a large supply on his own shelves. Production is regulated to prevent an over-supply of parts which may be superseded by new models.

Drill Steel—Perhaps one of the most important duties of the company's field

to the particular rock encountered has resulted in greatly increased drilling progress.

The work in the heading must be closely co-ordinated with that in the blacksmith shop. For example, in forging bits and shanks on hammer drill steel care must be taken not to overheat the steel, as it may become decarbonized and thus spoiled. Too high a forging heat results in excessive breakage of bits, shanks, and steels. Where possible an oil furnace is recommended for heating steel prior to sharpening, while the use of a drill-sharpening machine, operated by compressed air, speeds up the work and produces bits of uniform quality and size.

The company's representatives always impress upon drill sharpeners the desirability of allowing the steels, after they are forged on the bit end and on the shank end, to cool off before reheating for tempering purposes. With the company's Swedish drill steel forging heats should not be less than 1,850 nor more than 1,950 deg. F. If after tempering, the bits are too hard the edges may break or chip off and if too soft they flatten out. For medium hard rock, field service men suggest heating steel to about 1,450 deg. F. (cherry red) for the tempering process. In some cases where it has been found impossible to harden the bits properly, the trouble has been due to the presence of alkali in the water for quenching the bit. In such cases the suggestion is made that rain water be used in a tank provided with a water jacket for cooling. Where very hard bits are required, the tempering may be done in a brine solution. All hammer drill shanks should be tempered in oil at a dipping temperature when quenched of 1,450 deg. F. (cherry red).

Shanks—The company's inspectors lay great stress on the necessity for correct drill steels as a means of obtaining the maximum work from the

ing, which allows the steel to swing out of line with the direction of piston stroke. Any of these conditions, of course, concentrates the full force of the blow on a comparatively small area of the piston, resulting in excessive strain often followed by breakage. The field service men, during their visits, always make it a point to inspect drill steel shanks and to instruct blacksmiths in their proper formation and treatment. Stress is laid on having the shank dimensions correct, and in squaring off the ends the blacksmith is urged not to depend on his eye but to test the trueness of the surface with a T-square. Each shop is provided with wall charts outlining recommended practice as shown by sketches and explanatory text. As an aid in securing good results, the field service men supply the drill sharpeners with gages which show whether the shank is the right length and whether the hole (where hollow steel is used) is centered and of the correct size. Gages also are supplied to determine when a rotation sleeve or chuck is worn to the point where it should not be used further.

Holes for Water Tube—An additional important point in the formation of drill steel shanks for water-feed drills is to make sure that the hole in the steel is large enough to receive the water tube. If the shank is too soft the end will upset and cut off the water tube, and trouble also will be caused in getting the steel out of the chuck. The instructions of the field service men, therefore, include gaging the hole in the shank so that a steel may never be sent underground with the hole in the steel improperly formed. This is an important point, as the basic principle of the modern rock drill is the expulsion of the rock cuttings by a flow of water carried under pressure through the hollow drill steel. To insure proper and uniform punching of hollow drill steel a mechanical punch is manufactured

either for attachment to a drill steel sharpener or as an independent unit.

CONCLUSION

The foregoing notes indicate some of the points covered by the field service men during their visits of inspection. This is one manufacturer's conception of service to the users of his product. Back of the plan lies a realization that, in the end, the interests of both maker and user of equipment are identical—getting the most work done at the least cost.

Business Notes

BLAW-KNOX Co., Pittsburgh, announces the opening of a Buffalo, N. Y., office at 622 Genesee Building. J. C. McQuide has been transferred from the Pittsburgh organization as manager of the new branch, which will serve northern and western New York and adjacent territory in connection with the company's road-building machinery, clamshell buckets, forms, sectional steel buildings and structural steel.

Equipment and Materials

Elevating Platform Truck

Announcement is made by the Crescent Truck Co., Lebanon, Pa., of a new elevating-platform truck operated by an electric storage battery and having a pay load capacity of 4,000 lb. The truck is designed for use in factory aisles, at docks, and on warehouse floors, where the load to be moved is

placed on skids under which the truck platform is projected and raised 42 in., lifting the skid clear of the floor. The overall dimensions of the truck are: Length, 108 in., width, 39 in., and height, 43 in. The wheel base is 58 in. and the load platform dimensions 54 x 26 in. In its lowered position the platform top is 113 in. above floor level.

The machine has a two-wheel drive, a four-wheel gear and speeds of 6 miles per hour light and 4 1/2 to 5 miles per hour loaded. Separate motors are provided for propelling the truck and raising the platform.

Publications from the Construction Industry

Portable Hoists—SULLIVAN MACHINERY Co., Chicago, has published two new bulletins on its single-drum and double-drum portable hoists for scraper loading.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Canadian Building Permits Decline During September

Total Value At End Of Third Quarter
8 Per Cent Below Corresponding
Period In 1922

The value of building permits issued in Canada during the first nine months of this year showed a decline of eight per cent as compared with the corresponding period of 1922, and an increase of 21 per cent over the first nine months of 1921. The total for 1923 was \$105,625,554; for 1922, \$115,113,336, and for 1921, \$86,970,449.

The value of the permits issued in September showed a slight decline as compared with August and there was also a small decrease as compared with September of last year. According to reports from 56 cities the estimated cost of building work during September was \$10,485,613, while in August it stood at \$11,541,593, and in September, 1922 at \$11,424,119. There was, therefore, a reduction of \$1,055,980 or 9.1 per cent in the former and of \$938,506 or 8.2 per cent in the latter comparison.

Forty-seven cities furnished detailed statements showing that they had issued nearly 1,200 permits for dwellings at a proposed cost of approximately \$5,000,000. Some 2,900 permits were issued for other buildings at an estimated valuation of over \$4,800,000. The construction of several buildings is frequently authorized by a single permit; the number of buildings to be erected, therefore, would be larger than appears from the number of permits issued.

FOUR PROVINCES GAIN

Nova Scotia, New Brunswick, Quebec and Alberta showed increases in the value of permits issued as compared with August, 1923. The largest actual gain of \$882,752 or 35.3 per cent was recorded in Quebec, while Nova Scotia with a gain of \$75,630 or 275.8 per cent, registered the most pronounced proportional increase. Of the declines reported in the remaining provinces, those of \$1,437,093 or 55.1 per cent in British Columbia and of \$720,943 or 13.3 per cent in Ontario were most noteworthy.

In comparison with the returns for September, 1922, Quebec, Alberta and British Columbia registered increases in prospective building. Quebec, with a gain of \$444,507 or 15.1 per cent, showed the greatest increase. The heaviest loss of \$801,581 or 14.6 per cent, occurred in Ontario, but that in Manitoba of \$324,115 or 38.2 per cent was also pronounced.

Thirteen important cities showed gains in September building permits.

In preparation — "The Business Situation as Shown by Industrial Expansion," and "Water-Works Installation in 1922 and 1923."

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for, in Construction News, pp. 239 to 252, are the following:

Hotel, Tacoma, Wash., Citizens Hotel Corp., \$1,500,000.

High School, Hartford, Conn., \$1,200,000.

Pulp mill and wharf, Cap Rouge, Que., St. Regis Paper Co., Ltd., \$4,000,000.

Dam, Lake Cushman, Wash., Comrs. Light & Water, Tacoma, \$1,250,000.

Channel, Pueblo, Colo., Pueblo Conservancy Dist., \$4,000,000.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News pp. 239 to 252, are the following:

Apartment, New York, N. Y., Sherman Elwood Building Corp., \$1,110,000.

Bridge sub-structure, San Francisco, Calif., to Healy-Tibbitts Constr. Co., \$1,192,484.

Lock, Point Marion, Pa., U. S. Engineers Office, \$750,000.

School, Brooklyn, N. Y., to G. F. Driscoll, \$995,995.

British Metals Prices Advanced

The recent tendency in British wholesale prices is upward, particularly in textiles, food products and non-ferrous metals, according to reports received by the U. S. Bureau of Foreign and Domestic Commerce. The advance in metals, particularly, is taken as an indication of improved industrial demand, since continental competition has been held partially responsible for increased unemployment in the United Kingdom.

That British metals prices have paralleled American quotations, in several instances, is shown by the accompanying table.

Electrolytic copper was exactly the same price in Manchester, England, on Sept. 28, as in New York warehouses. Spelter, on the same date, was a small fraction of a cent higher in Swansea, England, than in New York. Brass tubing, however, was 1/4c. per lb. higher in New York than in Manchester.

Pig iron, fabricated steel and lead were somewhat higher in the American warehouses, compared with the English quotations. Copper tubing, however, was over 1c. per lb. higher in Manchester than in New York, on the same date.

COMPARATIVE METALS PRICES, SEPT. 28, 1923

	U. S. A.	England
Copper, electrolytic, per lb.	New York \$0.14	Manchester, \$0.14
Lead, per lb.	New York 0.075	Manchester, 0.0548
Spelter, per lb.	New York 0.06875	Swansea, 0.06875
Pig iron, basic, per gross ton	Pittsburgh, 26.90	Lincolnshire, 21.15
Steel structural, channels and angles, per lb.	New York 0.0364	N. E. Coast, 0.1087
Steel bars, per lb.	New York 0.0354	Manchester, 0.0203
Steel tank plates, per lb.	New York 0.0364	Midlands, 0.0203
Steel hoops, per lb.	New York 0.0519	Sheffield, 0.02538
Copper tubing, per lb. (base)	New York 0.245	Manchester, 0.25585
Brass tubing, per lb. (base)	New York 0.23	Manchester, 0.22743

Value Of October Contracts 17 Per Cent Heavier Than For Same Month Last Year

Falling Off of 7 Per Cent Compared With September—Water-Works, Industrial and U. S. Government Construction Gained

Contracts awarded on large engineering construction projects during October totaled \$161,276,000, a gain of nearly 17 per cent, compared with \$137,877,000 for the corresponding period in 1922. The October total, however, represents a decrease of about 7 per cent, compared with \$173,072,000 for September.

Minimum costs observed in *Engineering News-Record* on each class of construction are as follows: Water-Works, \$15,000; other public works, \$25,000; industrial construction, \$40,000 and commercial buildings, \$150,000.

Of the \$161,276,000 a total of \$3,530,000 represented Canadian awards which fell off heavily from the September level.

All classes of construction fell off during October with the exception of water-works, industrial building and Federal Government projects. Water-works awards gained 26 per cent in total money value during the month, while Federal Government construction increased nearly 16 per cent. Industrial lettings, totaling \$48,985,000, were over three times greater than those for the preceding month.

Among the large projects awarded during October were the following: A power station at Kearny, N. J., \$20,000,000; addition to plate glass factory at Ottawa, Ill., \$5,000,000; silk plant at Jacksonville, Tenn., \$4,000,000; 25 mi. conduit, Portland, Ore., \$2,571,404; hotel at Chicago, Ill., \$2,250,000; hos-

pital at Nashville, Tenn., \$2,000,000.

The actual physical volume of construction represented by October contracts is exactly the same as that of October, 1922; 17 per cent heavier than for the corresponding period in 1921 and 74 per cent above the volume of October, 1920, lettings.

Business Briefs

Call money easy but firmer at 4½@5 per cent.

Time money remains dull with all loans at 5@5½.

Record freight movement occurred on Oct. 17, when railroads moved more cars, both loaded and empty, than ever before on any one day in history of American railroads.

Planning to avoid a building crisis, the American Construction Council is urging that, where possible, all repairs and alterations be done this winter so as to avoid delays when the construction takes on a new impetus in the spring.

Engineering News-Record Construction Cost Index Number

November, 1923.....	220.90
October, 1923.....	220.30
November, 1922.....	188.60
Peak, June, 1920.....	273.50
1913.....	100.00

Engineering News-Record's Construction Cost Index

Number increased 0.6 points since last month, owing to slight advance in lumber. Prices of other basic building materials remained unchanged during the month. The average rate for common labor is still 54c. Thus, general construction cost is 17 per cent higher than one year ago and 19 per cent under the peak; it is 121 per cent above the 1913 level.

Engineering News-Record Construction Volume Index Number

Monthly

October, 1923 (4 issues of E. N. R.)....	127
September, 1923 (4 issues of E. N. R.)....	137
October, 1922 (4 issues of E. N. R.)....	127
1913.....	100
Yearly	
1922 (entire year).....	130
1921 (entire year).....	88
1920 (entire year).....	91
1913.....	100

Engineering News-Record's Construction Volume Index Number is 127 for the month of October, and 130 for the whole of 1922, as against 100 for 1913. This means that the actual volume of construction in 1922 (not the mere money-value of the contracts let that year) is 30 per cent above the volume of construction for 1913. Our monthly volume number, 127 for October, 1923, is really the increment of construction, and indicates the rate at which contracts are being let as compared with 1913 awards.

VALUE OF CONTRACTS LET IN THE UNITED STATES AND CANADA DURING OCTOBER, 1923

	New England	Middle Atlantic	Southern	Middle West	West of Mississippi	Western	Total United States	Canada	Total

Labor Rates and Conditions Throughout the Country

Record car loadings and an active retail trade throughout the country, offer somewhat of a contrast to the recent falling off in production of textiles and metals. Although the Japanese demand has stimulated the building materials market, industrial activity, generally, is uncertain and there has been some curtailment in employment.

The principal wage controversies now awaiting adjustment are among foundry, clothing and railroad workers

and derrickmen. A slight rise in living costs, due to higher food and clothing prices, tends to further complicate the wage situation. Rents of wage earners' houses are higher at present, than at any time during the last nine years, and are still rising, according to a nation-wide survey conducted by the National Industrial Conference Board.

The average rate paid common laborers (pick and shovel men) in construction operations, remains at 54c., the

same as for the last four months; the June rate being 53c. per hour, according to *Engineering News-Record* figures. Local conditions are as follows:

Baltimore—Scarcity of structural iron workers. Conditions among common laborers nearing normal.

Boston—Labor plentiful in all trades.

Detroit—Conditions normal. Labor supply a little more plentiful.

Minneapolis—Wages slightly lower in brick and tile plants.

Montreal—Slight scarcity of structural iron workers; plenty of other crafts.

New Orleans—Plenty of labor, skilled and unskilled. Carpenters and plasterers now on strike, demanding increase in wage scale. Contractors, however, have refused to grant demands.

New York—The only wage contro-

versy developing during the last month was a strike of marble carvers, cutters and setters. The marble workers have demanded \$11 per day as against \$10, which they agreed to accept on May 1.

Philadelphia—Supply of labor equal to demand.

St. Louis—Carpenters' wage rate, \$1.75 per hour, effective Nov. 1, against \$1.50 one month ago. Building and

Common Laborers' District Council planning to demand increase of 20c. per hour for 3,000 members, effective March 1. All classes of common laborers affected except plumbers' helpers, who received increase Oct. 1.

San Francisco—New building projects dropped off somewhat; building trades mechanics, however, all busy completing old contracts.

Monthly Prices of Construction Materials

Ups and Downs of the Market

Pig Iron—Market slow in Birmingham district despite low price of \$23 per gross ton for No. 2 foundry iron. Several thousand tons of foreign iron received during week. Average price about \$1 below last month and \$5 per ton under year ago.

Railway Supplies—Standard rails, \$43 per ton at Birmingham and Pittsburgh mills; light rails higher in St. Louis. Ties higher in Chicago. Railroad steel requirements heavy, particularly in plates.

Pipe—Demand active in wrought pipe; no change in discounts. Cast-iron pipe slightly lower in Chicago and San Francisco. Sewer pipe advanced somewhat in Boston.

Road and Paving Materials—Few changes in road oil and asphalt prices since last month. Mexican asphalt up 50c. per ton in Boston and down about the same amount in Detroit. Road oils lower in St. Louis. Gains in Texas and Wyoming crude oil output offset decline in California. Paving stone higher in Chicago, Boston and Philadelphia; wood blocks up in Boston and Chicago.

Sand, Gravel and Crushed Stone—Sand advanced 5c. per cu.yd. in Dallas and Cincinnati. Crushed stone, however, dropped 5c. in Boston and gravel 15c. per cu.yd. in Cincinnati during month. Changes due to local labor and transportation conditions.

Lime—Hydrated finishing, advanced 25c. in Birmingham. 50c. in Boston, \$2 in Atlanta and \$3.50 per ton in Dallas; Detroit reports decline of \$1 per ton. Hydrated common, up 25c. in Birmingham, \$1 in Boston and \$1.50 per ton in Atlanta; down \$1 in Detroit. Lump finishing, higher in Boston, Birmingham and Atlanta. Common lump, advanced 10c. in Atlanta, 15c. in Birmingham and Boston and 25c. per bbl. in Dallas; dropped 50c. in Montreal and \$1 per ton in Detroit.

Cement—Mill prices firm and unchanged. Very little fluctuation at f.o.b. points. Birmingham reports rise of 10c. and Boston, 12c. per bbl., against declines of 20c. in Dallas and 40c. per bbl. in Atlanta, during month.

Structural Steel—October steel demand showed improvement over preceding month. Steel pipe, sheets, tin plate and nails most active items in present market. Plates and shapes still at \$2.50 base; bars, \$2.40 per 100 lb., with few quotations under that figure. Railroad and ship plates form bulk of steel plate demand; structural material quiet.

Brick and Hollow Tile—Common brick, wholesale, at dock, New York, \$19@20, against \$20, one month ago and \$14@15.50 per M. one year ago. Drop of 50c.@\$1 in Birmingham, \$1 in Minneapolis and \$2 per M. in Dallas. Boston quotes rise of \$2 per M. Im-

ported brick not penetrating further than eastern seaboard. Hollow tile slightly lower in Minneapolis, Cleveland and Dallas, owing to lighter demand and lower fuel prices.

Lumber—Shipments gain, despite slight falling off in production and new business. West Coast Lumbermen's Association report sales of 27,246,902 ft. b.m. for export during week of Oct. 25. Pine timbers advanced \$1 in New York, \$2.50 in Dallas and from \$2 to \$4 per M. ft. in Boston; Chicago reports decline of \$1, Birmingham \$2, Detroit and Philadelphia \$2.50 per M. ft., in month. Douglas fir rose 50c. in Seattle and \$2 per M. ft. in Detroit; dropped \$3 in Philadelphia and \$6 in Denver since Oct. 4. Hemlock up \$2 in Boston and \$8 in Montreal; down \$3 in Philadelphia. Spruce advanced \$2 per M. ft. in Boston.

Explosives—Slight decline in 60 per cent gelatin dynamite in Dallas; no other changes.

Scrap—No. 1 machinery cast and heavy melting steel down \$1 in New York. Stove plate dropped 50c. in St. Louis. Slight advance, however, in railroad malleable cast in latter city.

Linseed Oil—Raw oil, 98c., against 95c. per gal. (5 bbl. lots) f.o.b. New York, one month ago. Advance of 4c. per gal. reported in San Francisco, during week. No changes in nineteen other cities.

Price advances since last month are indicated by **heavy type**; declines by *italics***PIG IRON**—Per Gross Ton—Quotations compiled by The Matthew Addy Co.:

LUMBER

Prices wholesale, per M. ft. b.m., to dealers in carload lots, f.o.b.

San Francisco—Prices of rough Douglas fir No. 1 common, in carload lots to dealers at yards. To contractors, \$2 per M. ft. additional.

	6-8 and 12 ft.	10-16 ft.	22 and 24 ft.	25 to 32 ft.
3x3 and 4...	\$40 00	\$41 00	\$42 00	\$45 00
3x6 and 8	40 00	41 00	42 00	45 00
4x6 and 8	40 00	41 00	42 00	45 00
3x10 and 12	40 00	41 00	42 00	45 00
3x14	42 00	42 00	44 00	46 00
4x10 and 12	40 00	41 00	42 00	45 00
4x14	42 00	42 00	44 00	46 00
6x10	24 Ft. and Under		25 to 32 Ft.	33 to 40 Ft.
6x14	\$42 00		\$44 00	\$46 00
8x10	47 00		49 00	51 00
8x14	42 00		44 00	46 00
8x14	47 00		49 00	51 00

New York and Chicago—Wholesale prices to dealers of long leaf yellow pine.

	New York		Chicago	
	20 Ft. and Under	22-24 Ft.	20 Ft. and Under	24 Ft.
3x4 to 8x8	\$49 00	\$50 00	\$44.50	\$46.00
3x10 to 10x10	53 00	54 00	50.50	52.50
3x12 to 12x12	57 00	58 00	57.50	59.50
3x14 to 14x14	64 00	67 00	63.50	65.50
3x16 to 16x16	69 00	70 00	71.50	73.50
3x18 to 18x18	83 00	84 00	81.50	83.50
4x20 to 20x20	93 00	94 00		

Wholesale price to dealers; to contractors, delivered from lighters or cars to job, \$5 additional. Short leaf pine costs \$3 per M. less.

Over 24 ft.—Add \$1 for each additional 2 ft. in length up to 30 ft. for sizes 12 x 12 and under, for sizes over 12 x 12 add \$2, for merchantable add \$2 to sizes 10 x 10 and under.

CHEMICALS—Water and sewage treatment chemicals, spot shipments in carload lots, f.o.b. New York:

Sulphate of aluminum, in bags, per 100 lb.	\$1 40@ 1 50
Sulphate of copper, in bbl., per 100 lb.	4 90@ 5 00
Soda ash, 58%, in bags, per 100 lb.	1 33@ 1 51
Chlorine, liquid, cylinders, 100 lb., per lb.	.08 1/2 @ .09
Hypochlorite of lime (bleaching powder) in drums, per 100 lb.	2 00@ 2 10

FREIGHT RATES—On finished steel products in the Pittsburgh district, including plates, structural shapes, merchant steel, bars, pipe fittings, plain and galvanized wire nails, rivets, spikes, bolts, flat sheets (except planished), chains, etc., the following freight rates are effective in cents per 100 lb., in carloads of 36,000 lb.:

Baltimore	\$0 31	Detroit	\$0 29
Birmingham	.58	Kansas City	.735
Boston	.365	New Orleans	.67
Buffalo	.265	New York	.34
Chicago	.34	Pacific Coast (all rail)	1 34
Cincinnati	.29	Philadelphia	.32 1/2
Cleveland	.215	St. Louis	.43
Denver	1 27*	St. Paul	.60

* Minimum carload, 40,000 lb.

Minimum carload, 50,000 lb., structural steel only; 80,000 lb., for other iron or steel products.

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING
AND CONTRACTINGE. J. MEHREN, *Editor*
FRANK C. WIGHT, *Managing Editor*

Volume 91

NEW YORK, NOVEMBER 8, 1923

Number 19

Beginning Again

PREDICTION as to the effectiveness of the move toward co-operation initiated last week by the committee of the four national engineering societies is dangerous. It may mean the start of real effective co-ordination of engineering society effort in this country; it may be only a repetition of one of its several well intentioned predecessors which varied from the almost unanimously acknowledged failure, Engineering Council, to the debatable and debated Federated American Engineering Societies. The new co-operative effort has this in its favor—that it represents real co-operation and not assumption of composite authority. The deliberations of the joint conference will not commit the engineering profession to any expression of opinion or to any combined effort but they will serve for rapid interchange of society opinion and, in those cases where opinion in the four major branches is unanimous, they will promote the simultaneous action of those four branches. Society independence and professional integration may thus both be served. Whether this will be successful or not depends partly upon the care with which the joint conference does its early work but more particularly upon the attitude of the societies themselves toward the recommendations of the conference.

Water-Supply Co-operation in Jersey

TWO weeks ago we noted that low rainfall and runoff in the thickly settled portion of Northern New Jersey, with consequent water shortage in a large section, had stimulated adjacent municipalities to join with Newark in the Wanauque development being carried out for it by the North Jersey District Water Supply Commission. This movement has grown so rapidly since our earlier note that already the applications call for such a total as to convince both the commission and the interested municipalities that the Ramapo should be developed alongside the Wanauque. This feeling is accompanied by a growing belief that there should be joint public ownership and a co-ordinated development of all the sources of public water supply in North Jersey, both for economy's sake and to ensure an equitable division of the water without the inter-municipal and the private corporation conflicts that have prevailed for many years past. Some such plan was strongly urged by Allen Hazen in his masterly report of two years ago. Mr. Hazen suggested the creation of a new commission for this purpose. Since then, a court decision ruling that Bayonne could not proceed with its proposed Ramapo development without obtaining the consent of the North Jersey District Water Supply Commission as well as of the State Conservation and Development Commission, has indicated that a new agency is not required in law. All these things point to a promising beginning of the solution of the serious water problem confronting northeastern New Jersey. There is water aplenty for all this territory. Its wisest

development may require supplementary legislation but the greater need has been such an awakening of public sentiment as would result in municipal co-operation to meet the common needs of scores of rapidly growing communities. That seems to have come.

Earthquake Effects

TAKEN together, the picture of Japanese building damage printed in this issue and the account of W. S. Sample, published last week, contain some of the most valuable information upon earthquake resistance and effects ever obtained. Previous earthquake visitations of modern cities have been far exceeded in violence by the recent one in Japan, and for the present it seems fair to assume that the Tokyo effects represent the maximum of earthquake action, for engineering purposes. It is a great satisfaction to know that the modern buildings fully withstood the shaking, so far as their framework is concerned. That the more rigid shell was cracked and broken in many places is not surprising, since forced distortion of any structure acts most severely on the least flexible elements. The earthquake study committee which has been formed by the American Society of Civil Engineers may succeed in discovering what is responsible for this cracking and how it may be avoided in future buildings, though at all events it is better to have a building cracked than shaken down into ruins. The subject is of primary interest of course to regions known to be visited by seismic disturbances; yet it is quite possible that such study will have equally useful bearing on methods of construction applicable to other regions. Strength and efficiency of construction are always closely related.

Capitalizing Traffic Congestion Cost

STRUCTURAL improvements to relieve traffic congestion are obvious necessities in most of our large cities. But such improvements cost money and the authorities are reluctant to enter into large capital expenditures when temporary alleviation can be had by the various expedients of signaling and manual control. Not infrequently, however, a proper analysis of cost will show that the capitalized cost of the expedient is greater than that of the major operation required to cure. Such an analysis is made for railway grade crossing improvement. When the capitalized cost of crossing flagmen begins to approach the first cost of a permanent crossover it is time to consider the construction of such a crossover. Take a similar situation in our cities. Traffic policemen are being demanded at more and more crossings. One such policeman a day costs the city the interest on \$50,000. At the famous Fifth Ave. and 42nd St. crossing in New York City six to eight policemen are constantly on duty for at least two shifts. The city could afford to spend \$800,000 for a structure here that would permit traffic crossing without control. These permissible first costs,

it should be noted, capitalize only the policeman charge; they take no account of the scattered savings, difficult to compute but no less existent, which would result from easy and rapid travel through our streets. Nor do they try to measure the immeasurable saving of life and limb that would result from a clear crossing.

A Bad Beginning

SITTINGS of Secretary Work's "fact finding commission" have begun, under that body's new name of Committee of Special Advisors on Reclamation. While we have had no illusions concerning the sincerity of purpose which led the secretary to appoint this body, in view of his disingenuous procedure in the ousting of Arthur P. Davis and his avowed purpose to smash the efficient administration of the Reclamation Service, we yet have felt hopeful that the committee would at least approximate to constructive and sound conclusions. This hope is seriously shaken by the method adopted by the committee. Opening its work by holding hearings, a lifeless method at best, it is doing the amazing thing of holding these hearings in secret. The very purpose of the committee's existence is to throw the light of publicity on the obscure and intricate subject of reclamation—and yet the committee itself shuns the light and does its work behind closed doors! Is it the committee's desire to command the public's confidence? The committee cannot gain or hold confidence by indulging in star-chamber procedure, certainly not in a subject that has become as embittered by personalities and political chicanery as the handling of reclamation by Secretary Work. It needs to change its method without delay, and work openly under the public eye. It also needs to protect its own good name by preventing the issuance of untruthful press reports of its secret hearings, such as have found their way into newspaper columns during the past week or two.

More Disorganization

EVEN while the Reclamation Service scandal is yet fully before the public, news comes that activities are under way in Washington which threaten a similar "reform" of other branches of the Interior Department. Investigations by secret agents—"inspectors" working by detective methods—are in progress, and by the example of what we learn of the activities of political "inspectors" in the Reclamation Service it is to be feared that disorganization and disruption of these other bureaus are only a question of time. To engineers the threat of serious injury to the efficiency of our national administration through the demoralization of such bodies as the geodetic and geological surveys will be apparent. But the matter is of public concern quite apart from its bearing on engineering interests. The new manager of a large industrial corporation who would seek to apply dark-lantern methods of the kind now current in the Interior Department would have a short and catastrophic career.

Contract Bond Reform

ALL attempts to set up standards of responsibility for contractors in road work will be largely futile as long as unrestricted bonding prevails. Given increasingly higher rates commercial bonding companies can extend the limits of risk almost indefinitely. Contract surety premiums have increased enormously in a decade. In pavement work there has been upwards of 1,000 per cent increase in 25 years. Surety com-

panies claim that their increased rates are justified by the losses. In rebuttal contractors and highway engineers contend that the losses complained of are due to unwise risks which are constantly being taken in the strife for business and that the high commissions paid agents tempt them to accept hazardous business and even to conceal the full hazards from their home offices. Whereabouts justice lies in the controversy need not be inquired at the moment. The facts are that almost any contractor can get a surety bond and that a rate of 1½ per cent on the contract price is an absurd charge for the public to pay for safety against the real risks of highway work. Some way of changing the situation needs to be found. It is proposed in the conclusions of the joint committee of the Associated General Contractors and the Association of State Highway Officials, ratified by both associations in convention last year, that negotiable securities be substituted for surety bonds and that 25 per cent of the contract price is sufficient security for any highway work not extremely hazardous. Until laws are changed this practice is not generally possible and in no event can the highway official refuse a bond, if it is offered, or the contract, if the bonded bidder has named the lowest price. The argument returns then to the need of reform in bonding practice if standards of responsibility for contractors are to be set up with any hope that they can be successfully applied in canvassing bidders.

Business Engineering

MORE or less jocularly we have called attention to a number of curious engineers who seem to swarm the country—"hot dog engineers" and "matrimonial engineers" and "business engineers." Some of those specialists were readily recognized but we must confess we were not able to discover what the "business engineer" was until the other day we ran across a circular from a reputable firm of engineers engaged in industrial work which contained the following paragraphs:

Three terms—"plan," "structural design" and "income"—are the key terms of business engineering. The "plan" for any investment building must be founded on something deeper than architectural considerations; it must rest on the fundamental service or production needs and the growth possibilities of the business. The "structural design" must not only be good architecturally and engineeringly, but it must also have a correct relation to production or service requirements, to load factors, and to the cost of construction and maintenance. But no matter how good a building or a plant may be architecturally, how well planned it may be from a construction standpoint, or how well suited to its service or production requirements, unless it has the right relation to the possible income from the investment, it is not good business engineering.

That, then, marks the difference between construction work and business engineering; one is building; the other is building relation to potential income and growth. One is a matter of blue prints, building materials and labor; the other embraces all of these things, and in addition the building in of sound investment values.

This contains excellent advice. We have only one quarrel with it. It sets up a distinction between engineering and "business engineering" which does not really exist and implies to the lay mind, to whom the circular is addressed, that engineering *per se* has no concern with economics but is merely the skillful putting together of materials into usable machines or structures. This, as all engineers know, is false. Engineering is essentially economics—it is doing for one dollar what any fool can do for two, not only in the spending of the first cost dollar but also in the continued spending of the operating and the maintaining dollar. This is elementary engineering science and engineers who pretend that by practicing it they are doing something ahead of the run of their fellows are not fair to their own profession.

Vibration in Hydraulic Turbines

IN VIEW of the progress in recent years in the design and construction of hydraulic turbines, with their sensitive automatic control devices and the nicety of balance that is now attained, it is a decided shock to hear of a large unit being actually installed with something so far wrong in its design as to prevent successful operation. Elsewhere in this issue reference is made to a 40,000-hp. water wheel which, on being put in service, vibrated so seriously that the power company shut it down and finally corrected the trouble, or at least reduced it to safe limits, by the comparatively rough method of decreasing the runner diameter 5 in. by cutting metal off the runner around its entire circumference with an oxy-acetylene torch.

A paper before the American Institute of Electrical Engineers, in discussing the case, points out that the vibration problem, which has come with large reaction units under high heads, has not been thoroughly understood, and states: "In cases where vibration occurred a cut-and-try system of remedying it was usually resorted to and as little publicity as possible given to the procedure." This is all too true. If aversion to publicity is allowed to prevent placing discoveries on record, progress toward a solution of difficulties is hindered. In this instance particularly it is of great importance that the profession have the benefit of what has been learned. The facts brought out in finding a solution for the trouble in this case have thrown new light on the necessity for avoiding certain relations or combinations in designing reaction runners and guide vanes. Also there was developed a method of measuring and studying vibration in large units on a comparative basis that will be of great value in making similar studies elsewhere.

The vibration of reaction wheels has not been sufficiently well understood. In some plants where it has occurred there has been resort to struts and mass concrete to brace and weight the unit to absorb the vibration. As individual units have been made larger and put under higher heads the problem has grown more serious and the time has now come when it must be reckoned with in design. Although some manufacturers have doubtless had a sufficient knowledge of the proper proportions and relations of certain parts of the unit to keep within safe limits, nevertheless the causes of vibration have not yet been analyzed to such an extent that they can be expressed by exact formulas. Much more study on the subject is necessary. Fortunately, and as a result of the incident already referred to, there has been developed what seems to be an excellent means of making accurate studies of turbine vibrations. This deserves the careful attention of other company engineers wherever large reaction wheels are used. The power company is the logical agent for conducting studies that deal with operating conditions; the power company has the men and the equipment at the plant and no one else has so much at stake.

The development of the large-size, high-head reaction wheel made it imperative that vibration be controlled. Nothing is to be gained by glossing over previous difficulties or attempting to evade the issue. As the result of the case described in this issue it is safe to say the power company concerned will go thoroughly into the question of possible vibration in planning for future units. There is therefore an object lesson in

this incident—now that the importance of keeping vibration down to a minimum is understood and since it is believed that this can be accomplished by proper design, there will henceforth be no excuse for failing to take vibration into account.

The "Modern" Highway System

EXAMINATION of the annual report of the Wayne County, Michigan, road commissioners always gives one an interesting hour, if for nothing more than to show the forward steps of an organization that for the past seventeen years has been proceeding on a consistent program of highway development. When we think of highways, our thought is chiefly of the road surfacing. Looked at from this point of view, the most spectacular part of the paving work of Wayne County is drawing to a close. Its concrete highway system, laid out to cover 25 per cent of the county's mileage, will, after the prosecution of a persistent program since 1906, be brought to a conclusion by the 1924 work. Of course, grading and improvement of the secondary road system will still go on for some years.

But does that mean that the Wayne County highway system is "complete"?

The recent report of the road commissioners answers that question, for the greater part of the report is not taken up with paving, but rather with bridge building, grade separation, and with such roadside developments as tree planting, tree trimming, the improvement of road intersections, the sodding of embankments, the disposition of the wires of the public utility companies, the placing of highway signs, and the improvement of the large natural parks which are co-ordinated with the highway system. In other words, though every square yard of hard surface paving planned for the county should be completed and though the surfacing of the secondary roads should be done, there is still work, much work, ahead of the road commissioners. Edward N. Hines, chairman of the commission, asked recently when its job would be done, gave this reply:

"It will not be done until every mile of road in the county is improved; until every bridge is made safe and adequate in width; until pedestrian paths are provided on the trunk lines; until all grades are separated; until the system is lighted; until all the ditches are closed; until public comfort stations are provided to take care of the traveling public in a sanitary way; until all of our roads are planted; until we have numerous public parks and playgrounds; until all poles are off the highways and all wires are underground."

He added, significantly, "A big contract, but we have made a start on all of these projects, all of which are a necessary part of our ideal of what constitutes a modern highway transportation system."

All counties and states are not ready to accept this broad definition of what constitutes a modern highway transportation system. As a people we have not dared to visualize the full meaning of complete road service. Indeed, there is too much to be done to get the elements of a system of improved roads to have warranted most of us in reaching ahead much further than is necessary to secure graded and drained roadbed and adequately paved surfaces. Meanwhile we need prophets and leaders in the great enterprise of road building and we have them in the Wayne County Highway Commissioners and their far-seeing chairman.

Reconstruction of Sixteenth Street Viaduct in Denver

Combination Steel and Reinforced-Concrete Structure Designed So As to Utilize Existing Portions and Salvage Old Steel

BY ELSIE EAVES

Civil Engineer, Secretary to Herbert S. Crocker,
Consulting Engineer, Denver, Colo.

SEVEN participants, five railroads, the street railway and the City and County of Denver, are paying jointly for the reconstruction, widening and straightening of the 34-year-old Sixteenth St. Viaduct in Denver, crossing the Platte River and numerous railroad tracks and carrying a heavy burden of street railway and vehicular traffic. Both design and construction features, particularly the sequence of carrying out the work, have been controlled by the number of organizations interested, their financial ability (two being in the hands of a receiver) and also by their operating requirements. Column bent spacing was fixed by existing track align-

its reconstruction became necessary to provide adequate connection with north Denver.

The Denver practice of financing structures of this kind is to apportion the cost by agreement among the utilities served. The railroads proposed to reinforce the old bridge and build a fireproof deck. At the same time the City and County of Denver presented an alternative plan for rebuilding in concrete, utilizing some 75 per cent of the steel of the old structure. As the railroad estimate did not provide new foundations, and as records were not available to determine the condition of the substructure of the old bridge, it was decided to adopt the city plan. The amount each participant should contribute was based upon the proportion of its frontage on the viaduct right-of-way and upon its traffic served. Since the Denver Tramway Co. and the Denver & Salt Lake R. R. were in the hands of receivers it was impossible for them to contribute their share of cash, but the city agreed to handle the Denver & Salt Lake R. R. share and permitted the Tramway Co. to provide equipment, yard facilities and labor in lieu of money.

The design was separated into five broad divisions: (1) new pedestal foundations, U-wall abutments and concrete river piers; (2) removal of the two deck-truss river spans and the substitution of two skew, four-rib, spandrel-column, concrete arch spans; (3) dismantling and remodeling of the steel in the original structure built in 1889 and the design of a concrete structure enveloping the re-used steel; (4) widening the old part to a 44-ft. roadway to correspond with the remainder of the new structure, strengthening, elevating to grade and remodeling without dismantling of the steel portion at the north end which was built in 1910 and (5) the

FIG. 1—CROSS-GIRDER REINFORCEMENT ASSEMBLED ON GROUND

Old hand-railing used as reinforcing is in position at the bottom of the assembled steel.

ment and the desire to re-use certain steel girders. Concrete girders were designed so as to utilize the old steel for reinforcing after thorough cleaning. Additional steel reinforcing columns and trusses were jacked up under a new heavy concrete deck to insure their taking proportionate load.

In 1889 the Denver City Cable Railway Co. constructed a 3,000-ft. steel viaduct, 34 ft. wide, on masonry footings across the Platte River and the railway tracks. In 1910 two bad grades at the north end were removed by extending the approach one block. In 1916, when the Denver Union Station was remodeled, the portion of the viaduct over the terminal tracks was rebuilt with four new through girder spans. This viaduct has been closed to vehicular traffic for some years but has been retained for street railway service. In 1921, however,

Traveler 1 at right moving backward on old structure removes steel behind it. No. 2 at left is ready to erect steel stringers on concrete bents constructed by the Tramway Co.

FIG. 3—TRAMWAY MIXER TRAIN ON TOP OF VIADUCT

Electrically-operated 10-ft. mixer attended by flat car equipped with batch cars in position to load mixer. Motor car used for switching is next in the train. In the background is the tower of the city's mixing plant. The mixer train is on the construction track and at the left is the

operating track for outbound traffic, both supported by the steel girders on concrete bents of the center portion of the viaduct. As soon as the outside portion on the right is finished the tracks will be interchanged and the outside portion on the left will be built.

widening, strengthening and remodeling without dismantling of the "Terminal Section."

As the first and second groups were of new construction they presented no unusual difficulties. In the third group the old steel girders and transverse floor beams were used as stringers under the street railway tracks in the new design, so that the span lengths were fixed by the steel lengths available. This portion of the viaduct crossed railroad yards where the track alignment was fixed and clearances were secured without yard changes. The construction in this group was entirely of concrete, except for the steel stringers under the tracks, a continuous girder design being used, with sections of from three to five spans between expansion joints of the split-belt type.

To enable the Denver Tramway Co. to operate cars over the viaduct before the entire structure was completed, the plan contemplated the construction first of the center portion carrying the track. The old hand-railing was used as reinforcement in the concrete cross-girders and old 48-lb. rails in the columns. While the weight was more than required, and the handling costs were greater, the low first cost made the use of this second-hand material attractive.

Jack Steel to Bear Load—In the fourth and fifth groups the new concrete decking and the heavier wheel loads made necessary steel columns and trusses to reinforce the existing structure. The problem of insuring that these new members carry their proportionate share of the load led to the plan of placing the center columns with a driving fit, pouring the superstructure, then jacking up the trusses under the load. By means of deflections, the amount each truss should be jacked up was found to vary from $\frac{1}{2}$ to $\frac{3}{4}$ in., depending upon its

length. The entire steel structure in the fourth group was jacked up from 0 to 10 in. to bring it to the new grade.

Construction and Progress—On Nov. 14, 1922, the Denver Wrecking Co. began removing the timber decking, closely followed by the Denver Tramway Co. removing the flooring between its tracks. The foundation contractor also began excavation. As the city planned to dismantle, remodel and re-erect the steel on force account under the engineer's direction, a city steel gang followed the floor wreckers, burning off rivets, backing them out and bolting the steel ready for removal. In view of the low salvage value of the 105-ft. deck trusses on the two river spans, their floor beams were removed, anchors loosened and struts and lateral bracing cut, so that by throwing a line over the top chord of the far truss and using a stiff-leg derrick to pull the span over sideways, the steel was dropped into the river bed, where it was cut into carload lengths and snaked out to be sold as scrap.

A network of water pipes, gas pipes and telegraph cables as well as many old, unused and broken lines was encountered by the foundation contractor. In many cases the design of special footings was necessary, and for several blocks the south pedestal footings and U-wall abutment footings had to be carried down 16 ft. to avoid a 4-ft. sewer. At the river several hundred feet of 24-in. water main had to be moved out of the way of the new foundations by the water department's forces.

Street Railway "Works Out" Its Share—The Denver Tramway Co. "worked out" its share of the cost of building and setting the forms, placing the reinforcing steel and mixing and placing the concrete for the center

The contractor's plant consisted of one mixer and one tower, the concrete being carted to alternate ends of the arch to secure the balanced pouring.

Widening—After contracts for the foundations and for the arch spans were let, there remained the building of the two outside portions of the main structure and the placing of the concrete decking on the north end section and the "Terminal" section. As the Denver Tramway Co. wished to place the concrete in the remainder of the viaduct, the city contracted for sand and gravel, made complete form drawings and contracted with a local milling company for the construction of forms ready to be set up. Cement was bought by the city for the entire job to insure proper proportioning.

FIG. 6—TYPICAL SECTION OF ALL-CONCRETE REPLACEMENT

A tramway flat car was converted into a light derrick car, with which column reinforcing cages and column forms (assembled on the ground) were lifted into place and reinforcing steel and forms were handled. The girder sections between expansion joints, amounting to as much as 264 cu.yd., had to be poured continuously. To expedite the work, the tramway concrete train was supplemented by a tower, the train on the bridge competing with the mixer and tower on the ground to see which could place concrete the more economically. The split-bent expansion joints in this section were not so easily constructed as in the center portion; each half was formed and poured separately.

The engineer for the city on this work, which it is hoped will be completed early in 1924, is Herbert S. Crocker. Heading his designing staff is Ira O. Thorley who worked out the details of the plan of remodeling and who proposed and designed the continuous girders and split-bent joints. John S. Means is resident engineer in charge of the field work. Frank B. Varnum, who built the foundations, and the C. S. Lambie Co., which subcontracted the arch spans to Rodgers & Pickard, were the only contractors.

Compressive Tests of Hollow-Tile Walls

AS A RESULT of some tests of hollow-tile walls, 6, 8 and 12 in. thick, 4 ft. long by 12 ft. high, tested for compression, the United States Bureau of Standards presents the following conclusions: (1) Walls built of high strength tile were set with great care by an experienced mason. They were undoubtedly much stronger than walls built under ordinary commercial conditions. (2) Great differences in strength of tile do not appear to have appreciable effects on the strength of the wall. (3) Stress failure of the thin walls was about the same as for the thick walls, showing there was no appreciable column action. (4) No

relation was found between the ultimate strength and the load at first crack. (5) Stress at failure, computed on the net sectional area, was remarkably constant with tile on end, being independent of the size of the tile. (6) Walls having the cells of the tile vertical had on the average more than twice the strength of those having the cells horizontal. (7) Walls loaded with an eccentricity of 2 in. over one-half the width of the wall had about one-half the strength of similar walls axially loaded. Apparently this ratio is independent of the thickness of the walls. (8) Excessively loaded walls failed by crushing of the tile under the bearing plate. (9) Due to the wide differences in the modulus of elasticity of the tile, strain-gage readings were of little use. In general the deformation across a joint was much greater than the adjacent tile, in many cases being twice as great. (10) No relation could be found between the modulus of elasticity for the wall and that for the tile.

The above information is contained in the United States Bureau of Standards Technologic Paper No. 338, this report having been prepared by H. L. Whittemore of the Division of Metals and Bernard D. Hathcock.

An Experiment in Earth Road Construction

Highway Extension Work by Purdue University Teaches Back-District Farmers Good Road Methods

BY BEN H. PETTY

Assistant Professor of Highway Engineering, Purdue University, Lafayette, Ind.

A UNIQUE experiment in highway extension work was made by Purdue University during the past summer in the southern part of Indiana. In the winter of 1921-22 the Agricultural Extension Department conducted a very complete survey of agricultural conditions in six counties of this end of the state. Some astonishing conditions were revealed. One was that very little can be done to improve the backward farming situation until an adequate system of roads is constructed to provide the farmers an all-year outlet to their produce market.

An improved road is a curiosity in many parts of this district. The writer has traversed so-called roads which ran for long distances in the beds of streams.

STARTING IMPROVEMENT ON EVANSTON-TROY ROAD

In many places outcrops of ledge rock make a series of steps on hills that are practically unsurmountable for automobiles. During a rain the earth roads are converted into mud holes which practically eliminate traffic until they are dried out. In winter there is apparently no bottom to the roads, it being impossible to traverse some of them even on horseback.

There are some improved roads of stone or gravel leading out of the larger towns for various distances, most of them extending only a few miles. More roads are being improved each year but it will be many years before this improvement can be extended adequately to serve the entire district. Due in large measure to the fact that road conditions are so poor, this district has not been developed to its possibilities. Therefore the property valuation is low and very little revenue is produced through taxes for road development. Hundreds of acres appear on the tax duplicate as \$10 per acre and some as low as \$3. This of course is in the more inaccessible sections; some parts are well developed and contain very valuable farm land.

The present conditions simply mean that the farmer who is not fortunate enough to be located along one of the few improved roads is isolated for several weeks or months of the year. The survey showed that some roads were impassable as many as six to eight months.

In endeavoring to relieve this situation an agreement was worked out between the Highway Engineer-

ing and Agricultural Extension Departments of Purdue University and the State Highway Commission whereby an engineer could be sent into this district to spend the summer in directing the construction of demonstration sections of earth roads. The arrangements were perfected in June, 1922, by W. Q. Fitch of the Agricultural Extension Department and the writer in co-operation with the local county agricultural agents in the six counties. These plans provided for the construction of short standard sections of earth road in each county by the aid of volunteer labor on the part of the interested farmers. The short sections were to serve as models to guide the farmers in extending the improvement.

During June two trips were made into the district and in company with the local county agricultural agents inspections were made of various proposed sites for demonstration work. Suitable stretches of road, varying from $\frac{1}{2}$ mile to $2\frac{1}{2}$ miles in length, were selected in each county where definite assurance of co-operation could be secured from the local farmers. The kind and quantity of necessary equipment available locally was ascertained and a tentative date for commencing

EVANSTON-TROY ROAD AFTER IMPROVEMENT

work was set conforming as nearly as possible to the desires of the interested farmers who were to do the work.

Under the leadership of the county agents, road booster meetings were held in these various localities, organizations were perfected and definite plans of procedure were worked out. Men living in the vicinity of the sections selected for improvement were interviewed by committees and their pledges secured to donate a certain number of days' work with teams or as single hands.

As an indication of the interest aroused, the case of the Rome-Derby Road in Perry County may be cited. To straighten and improve a half-mile stretch of earth road with a gravel surface, those interested pledged a total of \$1,300 to be paid either in cash or in work on the basis of \$1.50 per day for single hands and \$3 per day for teams. A large amount was pledged in Derby seven miles away. On only one other section were cash donations solicited, that being the Zoar road in Dubois County. About \$400 was secured mostly from Huntingburg merchants four or five miles away from the half-mile section being improved.

Professor R. B. Wiley, acting head of the school of Civil Engineering, arranged with J. D. Williams, director of the State Highway Department, for co-operation in the way of needed equipment in those districts where local equipment was insufficient or

lacking altogether. This co-operation aided materially in the successful prosecution of the work. The county highway superintendents and, in most cases, the township trustees co-operated splendidly.

The roads selected for improvement were all township roads in very bad condition. Practically all of the roads in this district are too narrow. The demonstration sections of earth road were built to a width of 20 ft. between shoulders, conforming with the standard county road width. On some of the roads there were no culverts at all and storm water had an unrestricted sweep across the roadway. Where culverts existed they were invariably too short, averaging about 12 ft. in length, thereby limiting traffic to a single track. On the improved sections the culverts were lengthened to the full width of the roadway.

In Indiana the township roads are under the supervision of the township trustees. The funds available for road work in the poorer townships are very limited, in many cases averaging as low as \$20 per mile per year. This accounts for the neglect of the roads in many localities.

The accompanying table gives the results of the sum-

COST OF EXPERIMENTAL ROAD IMPROVEMENT,
SOUTHERN INDIANA

County	Road	Length in Miles	Days of Labor		Material Purchased	Days for Tractive Power	Total Cost
			Hand	Team			
Crawford	Grantsburg-West Fork	25 ⁰⁰	6 ⁰⁰	*Dynamite			
	Riceville	\$2 00	\$4 00	\$6 00			\$80.00
	Wildlife	4 ⁰⁰	15 ⁰⁰	*Dynamite	4 ⁰⁰		223.00
DuBois	Huntingburg	107 ⁰⁰	103 ⁰⁰	Misc.			
	Zoar	\$2 50	\$4 00	\$164 00			847.50
	Jasper-Ireland	72 ⁰⁰	53 ⁰⁰	Oil on road			
Spencer	Evanston-Troy	77 ⁰⁰	78 ⁰⁰	*Misc.	1 ⁰⁰		
	Dale-Stendale	\$2 00	\$4 00	\$10 00	\$15 00 ¹		491.00
		\$30 ⁰⁰	\$10 ⁰⁰	Misc. ⁴	41 ⁰⁰		215.00
Warrick	Fiberfeld-Millersburg	6 ⁰⁰	12 ⁰⁰	*Culverts	3 ⁰⁰		
		\$2 00	\$4 00	\$50 00	\$20 00 ³		170.00
Perry	Rome-Derby	174 ⁰⁰	119 ⁰⁰	Dynamite			
		\$1 50	\$5 00	\$17.75			647.00
Pike	Petersburg-Oatsville	10 ⁰⁰	10 ⁰⁰		4 ⁰⁰		
		\$2 50	\$4 00		\$33 00 ²		197.00

* Estimated. ¹ Traction Engine. ² Tractor. ³ Truck. ⁴ 40 gal. gasoline @ 25c. = \$10.00, 1,000 ft. bridge lumber \$30.00, 100 lb. dynamite \$25.00.

mer's work. The total cost is based on the assumption that the volunteer labor was paid for at prevailing rates. The cost of engineering supervision is not included. The writer spent from one week to ten days in each county directing the work.

Conclusion—The summer's work as a whole was highly successful. The improvements received considerable publicity in the local papers and the position of Purdue University and the State Highway Commission was greatly strengthened in this district. The farmers have been shown what can be accomplished in standard earth road improvement with meager equipment and at very low actual cost. Undoubtedly these demonstration roads will stimulate similar improvements in these counties. The farmers have been taught to help themselves in the matter of road improvement and this is exactly what they will have to do to get better roads until such a time as revenue from taxation provides sufficient funds to finance such improvements.

To Investigate Arch Dams

ENGINEERING FOUNDATION'S committee on arch dam investigation has recently submitted a progress report. Two meetings were held in San Francisco, in the early part of the year, and a tentative program was formulated. The committee was fortunate enough to secure for the proposed investigation of arch and multiple-arch dams the active co-operation of the following parties who own or control dams: United States Reclamation Service; State of California; City of San Francisco; Pacific Gas and Electric Co., San Francisco; and Southern California Edison Co., Los Angeles. Furthermore the officials of the University of California, Stanford University, and Massachusetts Institute of Technology have offered the use of their testing laboratories and have assured the committee of other co-operation.

A search was first made for types of instruments which would be suitable for the proposed investigation. Some of the instruments required were readily obtainable in the open market, and others were ordered from manufacturers according to specially prepared drawings and specifications. The owners of dams co-operating actively with your committee agreed to furnish all the necessary instruments and to bear all the expenses incidental to a complete investigation of their dams in accordance with the program.

Dams Selected—In view of the considerable expenses involved in making continuous and accurate measurements on suitable structures, most of which are located far up in the mountains, it was decided to start on a somewhat limited scale and to include during the first season of field observations only structures for which the conditions for making measurements appeared to be particularly favorable. Consequently, the following dams were selected for the first part of the investigation: Hubbart Dam, Mont. (under construction); Clear Creek Dam, Yakima Project (both dams built by the U. S. Reclamation Service); Dam No. 6 of Southern California Edison Co.; Lake Spaulding Dam, Pacific Gas and Electric Co.; Lake Eleanor Multiple-Arch Dam, San Francisco; and the Lake Hodges Multiple Arch Dam, California.

The tests on each dam were placed in the immediate charge of a sub-committee of engineers who are particularly familiar with that dam. In order to co-ordinate the work on all dams local members of the main committee are acting as chairmen of the sub-committees.

Preliminary steps were taken for having laboratory tests made on models. Furthermore, several power companies have expressed willingness to consider financing the construction of a specially designed test dam, which could be tested repeatedly and finally loaded to destruction.

Professor C. Derleth, Jr., of the University of California, is chairman of the committee, and Fred A. Noetzli, Los Angeles, is secretary. Other members are H. Hawgood, D. C. Henny, W. F. McClure, M. M. O'Shaughnessy, H. Hobart Porter, F. E. Weymouth, Silas H. Woodard, Paul Bailey, R. P. McIntosh, and Wynn Meredith. The committee will be glad to receive information about interesting arch and multiple-arch dams and suggestions that will be helpful in its investigations. Several engineers in America and Europe have co-operated in this way.

Federal Land Reclamation: A National Problem

3. Agriculture on Irrigated Lands.

By CARL S. SCOFIELD

Agriculturist, U. S. Department of Agriculture

The Third of a Series of Articles on the History and Performance of the Great Government Adventure in Irrigation of the Arid Land of the West.

IN UNDERTAKING the utilization of the arid lands of the western United States through irrigation, conditions and problems have been encountered that are new to our race. Our agricultural people have been since the beginning of civilization accustomed to farming under rainfall. The engineers who have planned and built our irrigation works have had to meet and solve many new problems not only in connection with the construction work but more particularly in the continued profitable use of the water in agriculture. Irrigation farming may be older than any other kind of highly developed agriculture but the people of northern Europe who have contributed so largely to our population and occupied our agricultural lands have had no practical experience with irrigation. The engineers who constructed and operated the extensive irrigation works of antiquity in Western Asia and Northern Africa have left no written accounts of their work, and the problems and difficulties of the men who farmed those irrigated lands have not been recorded. There are evidences that irrigation was used both in North America and in South America long before the arrival of Columbus. In Peru and along the Gila and the Santa Cruz in Arizona, the discoverers found irrigation in use to a limited extent and it is now known that there were much more extensive irrigated areas that had long since been abandoned, as for example in the Salt River Valley of Arizona.

With us the development of irrigation farming has been for purposes of homemaking rather than to contribute directly to the volume of our agricultural products. In the valleys of Utah and in the foothills of California where irrigation was first undertaken about the middle of the last century, it was used to support pioneer communities. Later, extensions were made chiefly to provide support for families or communities largely engaged in other enterprises such as mining, stock raising, dry farming, or lumbering. It is only in recent years and to a limited extent that our irrigated lands have begun to produce commodities beyond the requirements of the immediate neighborhood and these commodities are chiefly specialties such as citrus and deciduous fruits, certain off-season truck crops, dairy products and long-staple cotton. The chief purpose that these lands have served is to support other industries and to make possible the effective utilization of adjacent dry lands.

The western half of the United States which includes practically all of our irrigated land is the great livestock breeding ground for the country. On its broad prairies and in the mountain parks and valleys our sheep and cattle are born and reared. Each year the wool goes East to market and the lambs and steers move into the corn belt to be fattened. The breeding herds and flocks stay on the ranges. But this western country is subject to great vicissitudes of climate, to prolonged droughts and to winter storms. These take

enormous toll from the breeding stock on the open range. A series of hard years such as recur almost every decade might sweep these ranges clean if it were not for those scattered valleys in which irrigation has made it possible to produce the feed and provide the shelter to carry the breeding stock through.

On the western Great Plains, on the high benches of the Great Basin, and in the broad valleys of the Snake River and the Columbia lie millions of acres of fertile land. This is the region to which we look for our great supplies of wheat. It was in this region that we produced the "food that won the war." But the rainfall that makes this production possible is extremely irregular. The only regular thing about it is that good seasons are followed by bad seasons. If the land is to be utilized in the good seasons there must be farmers on hand or nearby with work-stock and equipment to put in and harvest the crops. Or to put it another way, the stability of dry farming in the West depends upon the maintenance throughout the dry lands of irrigated sections to which the farmers may retreat and find support for themselves and their stock during the drier years. It is in these irrigated areas, small and scattered though they are, that we have some measure of insurance against the losses that would otherwise be disastrous to our national supply of meat and bread.

Development of Irrigation Projects

The first irrigation projects were small undertakings designed and constructed by individuals or by local co-operation, as by the pioneers of Utah. The investment of capital was small and soon liquidated. Later it became necessary to cope with larger engineering problems, to adjudicate and validate water rights and to undertake work that required large capital investments. This step involved the recognition that the irrigation works together with the lands they served with water should become security for the capital invested in construction. To be good security the lands must be productive, must be able to support a prosperous agriculture. For the larger projects which required expensive works for the storage, diversion and distribution of water, the money investment came to be a most important consideration. To repay this investment from the earnings of the land requires a long period of liquidation during which the agriculture must continue to be prosperous.

This situation has made it essential that in projecting a large irrigation enterprise the promoter or the engineer must take into account not only what it will cost to construct the works but also the character of the land to be served with the water, the quality of the water with respect to its dissolved salts, the character of the farmers who are to use the land and the water, and finally, those complex relationships of agriculture and economics which have to do with crop production and marketing.

The development of a successful irrigation project involves at least three different classes of problems, viz., legal, engineering, and agricultural. The last named group may be made to include not only the possibilities and limitations of crop production but also those matters that have to do with the settlement of the land, the type of farming, and crop utilization. The present paper deals with these agricultural problems.

The Land and the Water

It is an outstanding characteristic of our arid lands susceptible of irrigation that within a restricted area they are more variable in character and in potential productivity than the lands of humid regions.

This fact is due to the nature of their origin and formation. For the most part these irrigable lands have been made along river channels or delta cones. The soil deposited by flood waters may vary from gravel to clay within a few feet either laterally or vertically. Even where the surface topography is uniform the surface soil may vary in texture and depth between wide limits. It is generally true that the area of irrigable land in any project exceeds the available supply of water so that there is opportunity to select only the better lands for irrigation. There is often a strong temptation to the engineer who locates the distribution system to select compact and accessible units of land even though these may include soil areas of doubtful value as has been done for example on the Huntley, Shoshone, and Yuma Projects. The initial construction cost per acre of land served may be less if the water is distributed to the most accessible land, but when it comes to repaying these construction costs it becomes evident that productivity and not accessibility is the safer criterion for selecting land irrigation. The irrigation engineers of North Africa have found after years of bitter experience that their real problem is first to locate areas of good land in the desert and then conduct the water often long distances to reach that land.

Surface Topography—In selecting land for irrigation, a number of factors must be kept in mind. The surface topography must be such that the cost of leveling for irrigation is not prohibitive. Labor or money invested in preparing land for irrigation is just as definitely a capital investment as though it were invested in works for the storage or distribution of water. It sometimes costs as much as \$100 per acre to level land for irrigation though such cases are exceptional. But there are large units of land put under ditch where the cost of leveling is as much as \$35 to \$40 per acre. Land with a good surface topography may be leveled for \$5 to \$10 per acre. The cost of leveling the land may be actually greater than the cost of the water yet too often it is not taken into account in advance as one of the factors to be considered in selecting land for irrigation.

Texture and Depth of Soil—The texture and depth of the soil is no less important than the surface topography. If a soil is to be continuously productive under irrigation its texture must be such that part of the water applied may percolate downward past the root zone to carry away any excess of dissolved salts that would otherwise accumulate by the evaporation of the water from the soil or transpiration from growing plants. On the other hand, the chief function of the soil is to serve as a reservoir in which water may be stored for use by plants from one irrigation to the next. To do this effectively the soil must be not only

permeable to water so as to absorb water readily when irrigated but it should be deep enough and fine enough to hold several inches of available water within the root zone. Coarse sandy soils or a thin layer of good soil over a sand of gravel subsoil cannot hold a sufficient quantity of available water to provide the growing crop with a uniform supply.

Movement of Water at Roots—The third important factor of irrigated land has to do with the movement of water below the root zone. If the productivity of irrigated land is to be maintained there must be some percolation through the root zone in every part of the irrigated area. Unless such percolation occurs the dissolved salt brought into the soil by the irrigation water must in time accumulate in toxic quantities. In the ordinary course of irrigation, part of the water applied, and often too large a part, percolates through the root zone in the more permeable spots. Such excessive percolation is of no advantage but often quite the reverse. The aim of efficient irrigation is to distribute the water to the land in such a way and in such quantities that there may be some percolation through the root zone everywhere. In this way the excess of dissolved salts may be removed and an undue waste of water avoided. In any event conditions below the root zone must be such that the percolating water may be removed as drainage. Where such conditions do not exist naturally it must be possible to establish them artificially if the land is to continue productive.

The three essential features of irrigated land may be summarized as follows: The surface topography must be such as not to involve excessive cost for leveling; the texture of the soil must be such that it is permeable to water and sufficiently deep and retentive to hold several inches of available water within the root zone; and the subsoil conditions must be such as to permit the escape of water that percolates through the root zone.

Characteristics of Water—With respect to the character of the water, the essential requirements may also be stated simply. All irrigation water carries some dissolved material. The quantity may be small, as low as 100 parts per million, or it may be large, as high as 5,000 parts per million. In dealing with these proportions it may be kept in mind that an acre-foot of water weighs about 2.7 million pounds. The water that is applied to the land in irrigation is used or lost in three ways. It is evaporated from the soil, it is absorbed and transpired by plants, or it percolates through the root zone into the country drainage.

That part of it that is lost by direct evaporation leaves all of its dissolved salts in the soil, the part that is absorbed by plants leaves nearly all of its dissolved salts behind. It is only the water that percolates below the root zone that carries salt away. In this fact lies the significance of insuring that some water shall percolate downward through every part of the soil.

Owing to the fact that a large part of the water applied as irrigation is evaporated into the air either directly from the soil or from the leaves of plants, the soil solution is invariably more concentrated than the irrigation water. It is not uncommon to find that the soil solution in irrigated land contains as much as 5,000 parts or even 10,000 parts per million of dissolved material. This is a very different situation than exists in soils that are watered by rain or melted snow and

watered sufficiently to be leached frequently if not continuously. In such soils the solution contains from 100 to 1,000 parts per million of dissolved salts. When plant roots absorb water from the soil they do not take in the solution as it exists in the same way that a horse drinks water from a trough. They take the water from the solution and only such of the dissolved constituents as are needed for purposes of growth. As the soil solution becomes more concentrated it becomes increasingly difficult for the plant to absorb from it the water it needs. For most crop plants the limit of concentration of the soil solution is about 1.5 per cent or 15,000 parts per million. Crop plants differ somewhat in their limits of tolerance and they differ also as to the quantity of water they require. The average water requirement is probably not far from 400 pounds of water for each pound of dry matter produced.

The salts that are dissolved in the irrigation water or that exist in the soil solution have to be considered not only in relation to the crop plants but also in relation to the soil. The soil cannot be regarded merely as finely divided inert material in which the solution is held. It is an exceedingly complex system, some parts of which react chemically with the solution. As a result of these reactions certain constituents of the solution may combine with the soil and other constituents that were combined with the soil may pass into the solution. Such reactions are more pronounced when the solution is more concentrated. The results of these reactions between the solution and the soil may be manifested by pronounced changes in the physical condition of the soil as well as by changes in the chemical composition of the soil solution.

Permeability of Soil—The factor of physical condition that is most important in irrigated soils has to do with permeability to water. Permeability is directly influenced by certain of the reactions that take place between the soil and the soil solution. When a soil has been in contact with a concentrated solution in which the salts of calcium or magnesium predominate, the physical condition and permeability continue to be good if the concentration of the solution is reduced as by leaching with pure water. On the other hand, if the soil has been in contact with a concentrated solution in which the salts of sodium and potassium predominate the soil becomes puddled and its permeability is greatly reduced when the soil is leached with pure water. It has long been known that some irrigated lands become puddled or hard and impermeable to water. This condition has been thought to be due to action of the dreaded "black alkali," sodium carbonate. Recent investigations have shown that the soil may become puddled or impermeable from the action of sodium in the form of any salt. Even sodium nitrate has been shown to have the same effect as sodium carbonate. These facts make it important to take into account the character as well as the quantity of salts in irrigation water. Where the proportion of earthy bases in solution is less than the alkali bases, a condition that is almost certain to cause trouble, it is possible to change the balance of salts by treating the land or the water with gypsum.

There is ample evidence in our older irrigated areas of the significance of these differences in the quality of the water. There are extensive areas where through inadequate drainage the soil has become water-logged and salty and where complete and satisfactory reclama-

tion has followed drainage. The Rio Grande and North Platte projects afford striking examples of such restoration. There are other areas as in the valley of the Great Salt Lake in Utah where the land that was once productive became water-logged after a few years of irrigation and has remained impermeable to water and consequently unproductive even though elaborate drainage systems have been installed.

It is generally assumed that the occurrence of alkali troubles in irrigated land is due solely to the excessive use of water or the lack of adequate drainage. As a matter of fact an irrigated soil may become water-logged and unfit for crop production without becoming salty, though instances of this condition are uncommon. But it is not uncommon to find instances as in Southern California where the soil becomes salty or impermeable and unproductive without becoming water-logged or showing need of drainage. The development of such conditions is likely to be associated with the sparing use of water containing less calcium than sodium in solution.

Water-Logging—Many of the first irrigation projects, especially those established 20 to 30 years ago, were put in without any thought of the need of drainage. Some of these early projects soon developed troubles from underground water. These troubles were generally ascribed to the excessive and reckless use of water by the farmers and drainage relief was first considered merely as an expensive alternative to the more economical and efficient use of water in irrigation. Our irrigation engineers have been slow in appreciating the fact that the salts brought into the soil by irrigation water must be carried downward by percolation and outward by drainage or the productivity of the land would inevitably be ruined. It is not so much that underground water causes a rise of alkali as that it prevents the leaching action of irrigation water that is necessary to keep the soil productive.

From this it may be inferred that the character of the water used in irrigation may be a matter of the greatest importance in determining the time that the land may continue to be productive. This is a matter of concern not only to the farmer on the land but also to the agency that provides money on long term credits either for the construction of the project or as loans for the development and equipment of the farms. Irrigation works are designed and built to last for many years. It is clearly the expectation that the agriculture that these works make possible shall be as enduring as the works themselves. Yet it has been the sad experience in many localities that after a few years of irrigation the land becomes unproductive and must be abandoned.

The factors of the character of the soil and quality of water that determine sustained productivity under irrigation are almost infinitely complex. Some progress has been made in recent years in understanding them but the work is only started. Twenty years ago there was very little agricultural information available to engineers concerning the potential productivity of irrigated land or the effect on the soil of the salts dissolved in irrigation water. Facts bearing on these subjects are being accumulated by agricultural investigators working for the federal government and the Western states. The importance of these investigations is coming to be appreciated not only by engineers but also by

financial men and economists who have to consider the advisability of financing the rehabilitation of existing projects or the construction of new ones.

Crops and Cropping Systems

Farmers on irrigated lands have a wide range of crops from which to select. Almost every crop known on the continental United States is grown to some extent under irrigation. About half our irrigated acreage is now devoted to forage crops of which alfalfa is by far the most important. One-fourth of the land is used for cereals. Something less than 10 per cent is devoted to fruit crops and the remainder is used for such crops as sugar beets, cotton and truck crops.

There appears to be rather more of a tendency toward crop specialization among farmers on irrigated land than elsewhere. This is particularly true with the growers of citrus and deciduous fruits, certain truck crops, and sugar beets. There are certain definite advantages to be obtained from specializing in one or in a limited number of crops and there are certain disadvantages also in this system of farming. The chief advantages are that the farmer who specializes on one or a very few crops needs less equipment than the one who grows many different crops. It is also possible for him to become expert in his work. He may learn how to get good yields and to control the insect pests and plant diseases of one crop while he could scarcely hope to do so for a large number of crops. The outstanding disadvantages are that a one-crop system of farming does not provide continuous productive employment throughout the year and, with some crops at least, better yields may be obtained from a system of rotation of crops.

It is seldom possible to determine in advance of experimentation what crops or what system of cropping is best adapted to a newly irrigated region. It may take several years for a group of farmers on a new project to find themselves and to learn the difficulties and the possibilities of a new region. Their first crops will naturally be alfalfa and grain. Then as they become acquainted with local conditions and accumulate knowledge through experience, they will work into specialties or adopt a system of diversified crops grown in rotation.

This has been the course of events on several of the older projects as for example the Salt River, Yuma, and Imperial Valley projects in the Southwest. It became apparent more than fifteen years ago that alfalfa and grain crops could not be expected to bring returns on these projects that would justify the cost of production and pay the long haul to distant markets. Furthermore there was need of a crop requiring summer cultivation in order to control the weeds that became serious in fields devoted continuously to alfalfa and grain. To meet this need experiments were made under the auspices of the federal Department of Agriculture with long-staple cotton. This crop yields a product that is relatively high priced and can bear the cost of transportation. Its use in rotation with grain and alfalfa affords an opportunity to clear the fields of weeds and the seed, of which it yields 2 to 3 pounds for each pound of lint, is a valuable by-product both as a source of oil and as a feed for live-stock.

The production of cotton is now well established on all the important irrigated lands in the Southwest from the Pecos Valley to the San Joaquin. Its successful

establishment has involved the solution of a number of agricultural problems as well as the organization of the farmers for controlling supplies of planting seed, selling the crop, and financing its production. The returns from the crop have gone far toward making these projects prosperous and the incidental benefits, such as improved yields of other crops and community organization, have been well worth while.

Successful irrigation farming must involve relatively high returns from the land. The labor costs of production which include the distribution of water to the crops are higher than in ordinary farming. The fixed charges assessed for repaying the cost of constructing the irrigation works and for operating and maintaining them must be added to the ordinary fixed costs such as taxes and interest on investment. It is only by more intensive use of the land or by obtaining much larger yields that these added costs can be met if the products of irrigation farming are to compete in the same markets with the products of ordinary farming.

The working out of a system of farming best suited to an irrigation project is a problem which deserves co-operation between the engineering management, the bankers, and the farmers. Its successful solution is a matter of such great importance to the whole community that it merits the attention of the best intelligence the community possesses. It involves matters of crop production, of financing and of marketing. A compact, circumscribed community such as an irrigation project constitutes a definite social and economic unit like a large family. It may be in part self-sustaining but it requires many commodities it cannot or does not produce. In order to obtain these it must produce certain commodities for outside sale. What shall these be? How much of what is needed locally can be produced locally? Of the products that may be grown for outside disposal, which are best suited to the limitations of transportation? Such questions as these need to be clearly formulated and seriously considered, not only by the farmers themselves but by the whole community. In formulating these questions and in assembling the data needed for their consideration the engineer may render a very important service to the community. Such an undertaking calls for the clear and well-ordered thinking that characterizes the engineering type of mind.

Irrigation Farmers

It has been remarked above that there is a great diversity in the soil of an irrigated region. Such diversity is no less marked among the farmers. In any consideration of the factors that make for the success or failure of an irrigation project the character of the farmer must be taken into account. It is no less important than the character of the soil or of the water. When a new irrigation project is opened for settlement, people of all sorts and conditions flock in to take up the land. Some of them come with the expectation of making homes on the land and of making a living by farming. Many others have no thought of homemaking or of farming. Their aim is to get possession of land which may be sold later at a profit. In both classes one finds many individuals who know little or nothing of farming as well as those who lack the physical or mental qualities that are necessary to cope successfully with the new and often trying conditions of pioneer life.

There have been many serious misconceptions cur-

rent regarding pioneer conditions on newly irrigated lands. In many respects those conditions are less severe than those encountered by the pioneers who cleared and broke the prairies of the upper Mississippi valley. There is this difference, however, it takes more capital and more agricultural skill to develop and bring into production an irrigated farm than was required to make a self-supporting home on the humid prairies. The contrasts are more apparent, too, between the settled and orderly life of the older regions and the uncertainties of the new because of better communication. Modern pioneers to the new lands of the West are no less capable and no less courageous than their ancestors who settled Ohio and Kansas. Those early pioneers endured great hardships and made many mistakes. Many of them failed. With the lapse of time these mistakes and failures are largely forgotten and only the successes are in evidence or remembered. In the settlement and development of new irrigated areas there must be inevitably much hardship and many failures.

As the incoming settlers take up the land the initial conditions of diversity are emphasized. It is part of the equipment of a good farmer to be able to select good land and to appreciate its relative value. The natural result is that when the new region is finally settled, one finds the good farmers on the good land and the poor farmers on the poor land. While the situation is not peculiar to irrigated land, its consequences are made more conspicuous there because of the greater importance of community relationships and responsibilities. In an irrigated district each farmer is expected to contribute his share toward liquidating the cost of the project works and to the annual cost of operating and maintaining them. If he fails to do this, the burden falls heavier on his neighbors. If a few individuals in a community fail to meet their community obligations it is only natural that others, though possibly better able to do so, should mark time and wait to see whether the penalties for non-payment are really to be enforced.

The management of an irrigation project is essentially an engineering job. But the engineer whose lot is cast in such work finds his path beset with problems for the solution of which there are no formulas in his engineering handbook.

Sustained Productivity

There have been a number of instances both in this country and in the Old World where the productivity of irrigated land has been comparatively short-lived. In some of these the causes have been obvious, on others obscure. There appears to be no valid basis for the view sometimes advanced that irrigation farming cannot be continued indefinitely on the same land. Nor is there much foundation for the belief that irrigated lands are made increasingly productive by the salts carried in irrigation waters. Among the factors that influence crop yields, the so-called plant-food elements in the soil are probably not of the first importance. On irrigated lands as elsewhere, such factors as weeds, insect pests, and plant diseases are likely to be more potent in reducing crop yields than the lack of fertility as that phrase is commonly understood.

Irrigated lands may be made unproductive through the accumulation of salts in the soil or by the rise of underground water. These hazards are characteristic of irrigation and merit serious attention. The other

factors mentioned above, that contribute to reduced production, operate on irrigated land as elsewhere. It is probable that the chief justification for a rotation of crops is that the practice affords an opportunity to keep down weeds and reduce the ravages of insect pests and plant diseases. It is well known that certain leguminous crops such as alfalfa and clover leave the soil richer in combined nitrogen which may benefit succeeding crops. And nearly every soil responds in productivity when its supply of organic matter is increased as by the application of manure or by plowing under crop residues. It is sound agricultural doctrine to recommend crop rotation, the use of farm manure, and of green manure crops whenever possible. But none of these nor all of them together can be warranted to maintain or increase the productivity of irrigated land.

Where the quality of the water or the methods of irrigation are such that soluble salts accumulate in the root zone of the soil, an ultimate decrease in productivity is inevitable. The symptoms or apparent causes of such decrease may be very different with different crops. With some crops the symptoms are similar to those of drought or shortage of water. With others there may be shown an increased susceptibility to disease. Certain of the non-parasitic maladies or "physiological diseases" of orchard fruits appear to be associated with conditions of malnutrition which may be due to abnormal concentrations of the soil solution. There is very little that is definitely known concerning these causes of reduced productivity. It seems highly probable, however, that other causes than the exhaustion of the supply of plant food must be found if this problem as it exists on irrigated land is to be correctly understood.

The causes that contribute to rapidly decreasing productivity on irrigated land are now under investigation by a number of state and federal agencies. It is clear that those causes must be understood and remedies devised or the future of irrigation in this country is in danger. The investigations now most actively pressed have to do with the alkali problem and with those non-parasitic diseases that are so serious in sections devoted to orchard fruits. The progress so far made in these investigations is encouraging and there seems to be good reason for hoping that the agriculture of an irrigation project may be as permanent as the dam.

Live-Stock Industries

The focus of popular interest in irrigation farming centers on crop production, yet the welfare of the people engaged in such farming is largely determined by their success in using or disposing of their crop products. Though much of our irrigated land is well suited to, and is used for, the production of forage and grain crops, many of the projects are located far from large markets so that their products must bear heavy transportation charges. When such bulky products as hay and grain must be shipped long distances to market, the cost of transportation becomes a large part of the market price. Wherever it is possible to do so, these bulky products should be fed to live-stock on the farm or at least within the community where they are produced. It may cost \$10 per ton to ship hay or grain to market and \$20 per ton to ship butter or meat animals, yet it takes at least 30 pounds of hay or 5 pounds

of grain to make a pound of butter or a pound of meat.

There are, in addition, two other valid reasons for feeding the bulky crop products on the farm. The first is that it provides remunerative employment at seasons when the labor requirements of crop production are low. The second is that farm manure is unquestionably helpful in maintaining crop yields.

A large number of irrigated areas are located in the midst of extensive areas of range land or between the range lands and live-stock markets. Such advantages of location should be utilized as fully as possible. The products of the irrigated lands such as hay, grain and beet tops are now used extensively for wintering range stock or for partly finishing cattle and sheep for slaughter. There are certain hazards and disadvantages to the use of crops in this way due to fluctuation of demands and of prices from season to season. In consequence the profits may be large one season and the losses may be heavy another season.

Returns are much more certain and in the long run, may be fully as good, where the forage and grain crops are fed to dairy cows and hogs. Dairying and hog production fit together well because the hogs make good use of skim milk and buttermilk which are by-products of dairying. Climatic conditions on many of the projects are well suited to these industries. Irrigated pastures of mixed grasses and clover for dairy cows and alfalfa pastures for hogs provide cheap, excellent summer forage. These conditions give our irrigated land advantages which may more than offset the handicap of distance from market and enable them to compete successfully with the dairy sections of the East and Middle West. In fact the center of the dairy industry is moving westward and on several of the northern and intermountain projects dairying is proving to be the way to economic salvation.

On some of the projects, dairying is made difficult or impossible because of the lack of suitable supplies of water for domestic and stock use. Where there is no underground water available or where it is very salty, it is not easy to carry on dairying. This is a fact which merits the attention of irrigation engineers, for the difficulty, where it exists, is one which they should find a way of overcoming.

Economics of Irrigation Farming

In a time like the present when agriculture is in a state of depression it is particularly difficult to formulate conclusions concerning conditions on the isolated and widely scattered irrigated areas. On many of them the pinch of deflation has been most distressing, on others it has been much less acute. On the whole, it appears that where the system of agriculture was fairly well balanced and particularly where dairying and associated live-stock industries were well established, there has been little downright hardship. There has been a pause in the expansion of operations and of credit that characterized the war period. Land prices have declined sharply, production less sharply.

There are two different points of view from which irrigation farming has to be considered. One is from the standpoint of the individual who is or may become engaged in it and the other is from the standpoint of the country as a whole. Farming under irrigation may be compared with dry farming which is often carried on nearby under similar climatic conditions or it may be compared with the more intensive farming that is

possible under conditions of ample rainfall. When compared with adjacent dry farming, the chief differences are that the cost of production is higher per acre under irrigation, and consequently the returns must be higher than for dry farming if the enterprise is to be profitable. An assured supply of irrigation water reduces the hazard of drought but it does not protect against such troubles as hail and frost and the ravages of insect pests and plant diseases. The fixed and labor costs of farming with irrigation are so much greater than with dry farming that irrigated lands cannot be expected to compete successfully with dry lands in grain production.

The slightly larger yields obtained by irrigation do not justify the increased cost of water and labor. Each acre of irrigated land must be made to yield two or three times as much in crop value as dry land to make it pay. Comparisons between irrigated land and other equally expensive land in distant parts of the country are not satisfactory. There is a tendency to rate irrigated lands at prices rather above those of lands of equal productive capacity in humid regions, notwithstanding the fact that the labor cost of crop production is substantially higher under irrigation. The implication is that the agricultural value of an assured water supply is probably overestimated. If there is to be any material extension of irrigation in the West such extension should be determined largely by the needs of western markets for the products of irrigated land. It is not to be expected that these isolated lands located so far from eastern consuming centers can compete with eastern farms in such crops as potatoes and hay. In any event there is need for the greatest care in selecting the land to be irrigated. The future will undoubtedly see less irrigation of land of doubtful productivity.

Home-Making Value—From a national standpoint our irrigated lands have a value far greater than that of the contribution they make directly to our supply of agricultural products. These lands provide farm homes for possibly 100,000 families. They make it possible to utilize enormous areas of arid and semi-arid land for pasture and for grain production which could not otherwise be used.

These considerations cannot be overlooked in taking stock of the present situation or in dealing with the policy of future extensions. It seems altogether probable that the construction costs of the projects that remain to be built will be higher than for existing projects. While it is doubtful if present agricultural conditions justify the rapid and large-scale extension of the irrigated areas in the West it is true that the local requirements of other industries and developments appear to justify a steady forward movement in irrigation construction. There are many projects, large and small, yet to be built. Conditions change from year to year in this new country. Factors that determine the feasibility of a project are influenced by these changes. Meanwhile there is every reason for maintaining and protecting the welfare of the projects already built and of solving those problems which stand in the way of their continuing prosperity.

[Further articles in the series will deal with past experiences and problems of reclamation and with future development. In next week's article Dr. F. H. Newell will summarize the twenty years of achievement in reclamation. The following week George F. Kreutzer will discuss land settlement problems.—EDITOR.]

Locomotive Shop Served by 180-Ton Crane: M.-K.-T. R.R.

Transverse Track Layout—Main Building Houses All Shop Facilities—Enlargement and Future Transfer Table

IN A LARGE steel-frame locomotive repair shop recently erected at the Bellmead terminal of the Missouri-Kansas-Texas R.R. at Waco, Texas, the engines will enter and leave the building on yard tracks and all interior handling of the engines will be done by an overhead crane of 150 tons capacity. This arrangement avoids the expense of a transfer table, but the plans provide for such a table when the shop is enlarged to double its present capacity of twenty engines per month. The present and future shop layout is shown in Fig. 2, and directly behind the main building is the engine terminal.

The transverse type of arrangement of shop tracks and pits was adopted after consideration of such factors as man travel, handling of materials and engine parts, concentration of work of similar character, supervision of the shop and the adaptation of the present construction to a compact plan for future development. As shown in Figs. 2 and 3, the main part of the shop has two longitudinal bays, an 80-ft. erecting bay and a 71-ft. machine bay. Two overhead traveling cranes serve the erecting bay, the upper one being a 75-ft., 180-ton crane to handle locomotives and the lower one a 15-ton crane to handle material. There are fifteen repair pits, 50 ft. long and spaced 25 ft. c. to c. The pit tracks are extended 8 ft. into the machine bay, so that in front of the engines there is space for wheels within reach of the 15-ton crane of this bay which carries the wheels to and from the machines or the storage platform.

Two track connections are provided. One of the pit tracks at the south end is connected to a yard track and at the north end a through track extends across the shop. Engines entering in this way will be picked up by the 180-ton crane and placed at the assigned repair

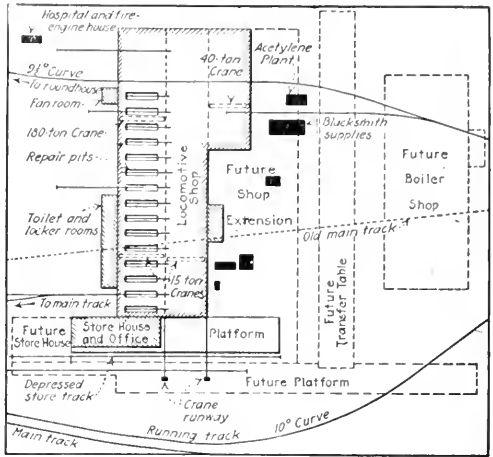

FIG. 2—NEW SHOP LAYOUT AND FUTURE EXTENSIONS

pit. In the same way, completed engines will be picked up and placed on one or other of the tracks for removal from the shop.

In the enlargement of the plant for its ultimate capacity of handling heavy repairs to forty engines per month, the shop will be widened instead of lengthened, each transverse track then having two pits. Thus there will be two 80-ft. erecting bays with two 71-ft. machine bays between them, each 80-ft. bay having a 180-ton crane for handling the engines. At the same time a transfer table will be provided in front of the new part of the shop and will serve both the repair shop and the future boiler shop, which will be 352x142 ft., located as indicated in Fig. 2.

Economical operation of the shop as now built and provision for future development with a minimum expense for interior rearrangement of tracks and pits were main factors in the design of the building. An outstanding feature of the work as now built is the concentration of all the principal shop facilities under one roof. The main building, which comprises the erecting and machine bays, is 477x156 ft., with a blacksmith and tank shop in an extension 202x71 ft., served by a 40-ton crane. At the rear of the erecting bay is an addition containing the toilet, locker and wash rooms. The boiler shop occupies the four north bays of the main building, next to tank and blacksmith shops.

FIG. 1—LOCOMOTIVE SHOP AT WACO, TEXAS; MISSOURI-KANSAS-TEXAS R.R.
The long steel building contains erecting, machine, boiler, tank and blacksmith shops. Storehouse and office building at right. Locker rooms in low structure behind main building. Power house at left.

FIG. 3—CROSS-SECTION OF REPAIR SHOP

At the opposite end is a two-story extension 152x50 ft., with store rooms on the lower floor and the shop office and tool manufacturing room on the upper floor. A platform for the storage of castings and heavy articles adjacent to the storehouse is served by the 15-ton traveling crane of the machine bay. This crane passes through the end of the building and its runway extends over the storehouse platform and track, so that wheels and heavy castings can be handled directly between the car or platform and the shop machines. This layout of the several departments is planned with a view of providing the most convenient handling of material and reducing to a minimum the amount of man travel.

Steel-frame shop construction consists of columns

spaced 25 ft. c. to c. longitudinally, connected by struts and girders and supporting the roof trusses and crane runways. In the lofty erecting bay the columns are offset near the top to form seats for the girders of the 180-ton crane; the 15-ton crane has its outer runway carried by flanged members forming offsets on the columns, while the inner runway is carried by brackets on the columns. The two lower bays have a modified pond truss or sawtooth roof arrangement with hinged sash on the glazed fronts. Hinged sash is provided also along the top of each side of the erecting bay. Steel sash with factory wire-glass composes almost the entire wall area, with ventilating sash in many of the panels. The ends, however, are partly of brick. Track entrances are fitted with swinging doors of steel frame and steel sash. The roof is of cement tile laid on the purlins and covered with composition roofing. Mastic surface on reinforced concrete is used for the shop floor. Electric current for power and lighting, purchased from the Waco plant of the Texas Power & Light Co., is distributed by cables and conduits laid in floor conduits. New machinery equipment will be used throughout, with individual motors for the tools and other machines. A circuit with self-registering apparatus provides for checking machine performance. For heating the main shop there is a fan system by which air taken from the outside is warmed by being passed over steam radiators and then blown through underground ducts to vertical pipe branches with discharge hoods about 8 ft. above the floor. Radiators for direct steam heating are used in the offices and store room. Steam and compressed air for the shop and engine terminal are supplied from a power house with two 328-hp. boilers, two air compressors of 2,000 and 500 cu.ft. capacity and duplicate fire pump equipment. Oil fuel is used, but the plans provide for future coal and ash handling facilities if these should be necessary. This building is of brick and steel, with an 8-ft. concrete smokestack 177 ft. high.

Minor works now being built as part of the shop plant include a supply building for the boiler and blacksmith shops, a paint shop, fire engine and hose house, first-aid room and a brick lavatory and locker room for the roundhouse employees. For safe and convenient communication between the plant and a city street a concrete subway 8x8 ft. and 355 ft. long has been built under the intervening freight yard. At the rear of the repair shop is the engine terminal, with 15-stall roundhouse, back shop, two ashpits and facilities for supplying the locomotives with water, sand and fuel oil.

Preparation of the site required about 140,000 cu.yd.

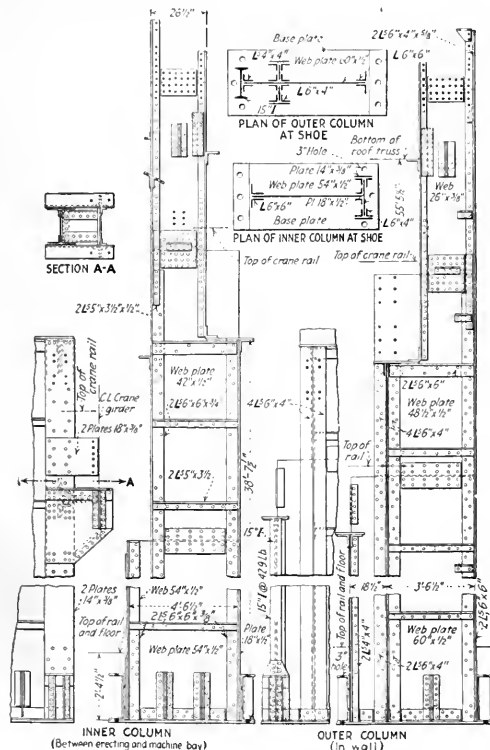

FIG. 4—COLUMNS AND CRANE RUNWAYS

of grading and about a mile of relocation of the main line, the old main track now forming the east approach to the shop and terminal plant. The general contractor for the building was H. D. McCoy, Cleburne, Texas; grading and concrete work, including foundations and shop pits, J. E. Hutt Contracting Co., Kansas City, Mo.; furnishing and erecting structural steel, Mt. Vernon Bridge Co., Mt. Vernon, Ohio; electric power installation, Beckett Electric Co., Dallas, Texas.

This Bellmead shop plant represents the last item in an extensive program of shop, yard and engine terminal improvements carried out on the Missouri-Kansas-Texas Lines during the receivership which ended early in 1923. All design and construction work are under the direction of F. Ringer, chief engineer, M.-K.-T. R.R.; assisted by J. M. Metcalf, principal assistant engineer; A. L. Sparks, architect; and M. C. M. Hatch, mechanical engineer. E. W. Metcalf is engineer in charge at Waco. The shop itself is estimated to cost \$1,700,000.

A Study of Vibration in Francis Type Water Wheels

Serious Vibration in 40,000-hp. Unit Cured by Increasing Runner Clearance—Device Measures Pressure Variations

A PAPER on vibration in Francis turbines was presented at the Pacific Coast convention of the American Institute of Electrical Engineers held at Del Monte, Calif., early in October, and was frankly discussed by manufacturers and power company engineers with the result that facts of great importance in the field of water-wheel design were brought out. The paper, by Roy Wilkins of the Pacific Gas & Electric Co., was entitled "A Study of Irregularity of Reaction in Francis Turbines." The following is a resumé of chief points of the paper combined with notes on the discussion from the floor of the convention as reported by a member of *Engineering News-Record* staff. One point not mentioned in the paper or in the discussion, but which should be pointed out so that the reader may grasp the situation, is that the turbine in question has a capacity of 40,000 hp.

The power company found a newly installed Francis turbine which had excessive vibration and proceeded to develop means of studying and analyzing the causes. The vibrations were found to be caused by changes in hydraulic pressure and to have a period in the order

FIG. 1—DIAGRAM OF CONNECTIONS IN THE RECORDING DEVICE

of electrical frequencies commonly used; hence they could be recorded by standard oscillograph methods. A device was built for measuring these pressure variations which consisted of a 1½-in. pipe union carrying a diaphragm of spring steel to the center of which was attached an arm extending to a pair of microphones of the variety used in wireless transmitting sets.

The outer elements of these microphones and a wire grounded to the union, as shown in the diagram, formed an elementary bridge with microphones and batteries as members and the oscillograph element as detector. This device could be tapped into turbine casing or penstock at any convenient point, a ½-in. connection, if not too long, being ample to actuate it. In most of the records made with the oscillograph the vibration of a 60-cycle wave was also recorded simultaneously on the sensitized surface for purposes of comparison.

The first tests were explorations of pressures on the runner vanes. These were made by the use of a Pitot tube traveling with the runner and passing to the center of the draft tube whence a packing gland made connections leading out to the device described above. By filling the rotating tube with air under pressure and then closing it at the instrument end, the air is trapped under the water pressure in the turbine and centrifugal action and leakage are minimized. In this way the whole face of the runner entrance was explored under actual operating conditions. Records were made of pressure variations occurring at various points in the revolution.

Having completed an exploration of the unit that vibrated excessively, the newly developed device was used to test other reaction turbines of the system, the idea being to compare the amount of vibration with features of design in several turbines under different conditions of load, head, etc., to determine, if possible, what features or conditions caused excessive vibration.

FIG. 3—RECORD OF RESONANT VIBRATION—THE OBJECTIONABLE SORT

This unit had 19 runner vanes and 20 guide vanes. The hum was apparent in both powerhouse and penstock. The generator of 5,000 kw., was 220-lb. pressure and 450 r.p.m. The upper curve is a 60 cycle wave recorded simultaneously for comparison.

FIG. 4—RECORD OF IRREGULAR VIBRATION—THIS WAS NEITHER AUDIBLE NOR HARMFUL

This unit had exactly the same scroll case, speed, water pressure and capacity as the other unit, but had 17 runner vanes and 20 guide vanes. The pressure variation shown is as high as in the other case, but there was no harm or vibration.

The final conclusion was that vibration in the unit giving trouble would be decreased by increasing clearance between the guide vanes and the turbine runner. It was decided to do this by cutting down the runner with an oxyacetylene torch. The cuts were made on the 15-in. face of the runner vanes where the metal was $1\frac{1}{2}$ in. thick, a $15 \times 2\frac{1}{2}$ -in. piece of metal being taken

FIG. 2—LOCATION OF PITOT TUBE IN RUNNER

off each vane, thus decreasing the runner diameter by 5 in.

This change increased the thickness of the water ring around the runner and very materially decreased the vibration. How this change has affected the efficiency of the unit and whether a new runner, finished in the shop to the smaller diameter, is to be substituted later, was not announced but at least the information brought out establishes the fact that most of the vibration was eliminated by increasing the thickness of the water ring around the runner.

Tests made on this and on other units led to the

conclusion that a sufficient thickness or width of the water ring around the runner is essential if harmful vibration is to be prevented. The power company interpreted their tests to indicate that if the water ring was thick enough the shape of the guide vanes was not important. This latter point differed from the conclusion of the water-wheel manufacturers as expressed at the convention, their tests and experience indicating better results with improved guide vane design.

Until recent years irregularity of reaction has been of little importance and has been treated as a more or less necessary evil. However, the danger of vibration increases with the head, and features of design satisfactory for low heads may give trouble under high heads. Uneven or irregular vibrations do not set up a condition of resonance and therefore are less audible and less injurious to the equipment than uniform pulsations which cause resonance and permit a maximum amplitude of vibration. For this reason certain limitations should be observed with regard to the relative number of guide vanes and runner vanes. If there are one, two, four or six more runner vanes than guide vanes, once every revolution, due to the vernier effect, a corresponding number of runner vanes simultaneously pass guide vanes, thus harmfully combining the effect of pressure changes due to the transit from the leading to the trailing side of runner vanes. On the other hand, with three, five or seven more runner vanes than guide vanes, the vernier effect occurs irregularly and although there is the same combining of pressure changes, these combinations recur at irregular intervals and cannot do the harm that results from resonant vibration.

The entrance angle and the amount of change in direction which the water is obliged to make between guide vanes and runner is another factor in the complex cause of vibration. There must not be; at any gate opening, necessity for a change of direction in the flow of water between guides and runner greater than can be accomplished without disrupting stream lines. Of course the permissible limits of this angular change decreases with decreased clearance and with increased head.

Reference was made in the discussion to vibration in large units under low head that had been muffled by heavy bracing; there was frequently repeated commendation of the device for recording turbine vibration described in the paper and a general agreement that much more study of the subject was needed particularly with the co-operation of power companies and water-wheel manufacturers.

A British Narrow-Gage Railway

A 12-mile line of 23½-in. gage has become a part of the system of the Great Western Ry., England, by the recent consolidation of British railways. This is the Vale of Rheidol line, in the mountainous part of Wales. With one continuous grade of 2 per cent for 6½ miles, engines of relatively high power are required and the Great Western Ry. shops have recently built two 25-ton side-tank engines of the 2:6:2 type having a tractive effort of 10,510 lb. Double-truck open cars are used in summer, having the roof supported by light posts and carrying curtains to be let down in wet weather. Each car, 32 ft. long and 6 ft. wide, accommodates 48 passengers on cross-seats, an aisle or gangway being left along one side.

Through the Reclamation Country

By F. E. Schmitt

Associate Editor, *Engineering News-Record*

THIS is the sixth of the series of letters written by Mr. Schmitt during a journey recently made through the West in which he visited irrigation projects, studied developments, and interviewed builders, operators and settlers, in order to present to our readers the actualities of reclamation as revealed to an unprejudiced investigator.

The series of letters began in the issue of October 4.

Delhi, Calif.

HERE at Delhi is located the second and newer of California's state-aid irrigation settlements. Much can be learned here about the difficulty of getting under way on an irrigated farm. It puts emphasis on the fact that the settler's money problem at the time of first starting out is one of the most difficult elements of irrigation development. But this fact is apparent on any reclamation project; few or none of them are fully settled up, and starting up may be seen in all its phases, in addition to which its long-time effects are more or less evident. It seems that many of the troubles and bitternesses existing on the projects trace back to the initial money difficulties.

A banker in a project town told me, in getting down to brass tacks on reclamation troubles, "This irrigation farming isn't a poor man's game. The man who has only \$1,000 shouldn't expect to come here and make a go of it." And Walter E. Packard, superintendent of the Delhi settlement, said something similar in speaking of how he assures himself not only that the intending settler is suited for farming but also that he has sufficient capital: "The financial problem of the settler is the most important one we have to deal with in developing our project."

Estimates made by various men on reclamation projects indicate that 30 to 35 per cent of the original settlers are still there, or that about twice as many as are now there have come and gone again. Since some few left because they could sell at a profit, this probably means that there have been two "crops" of settlers. Many of the first crop were squeezed out by the consequences of trying to start out without money.

Initial Money Needed—It costs more to start up farming under irrigation than elsewhere. But most settlers come to a reclamation project with very little money to spare. On a very optimistic guess based on a few statistics, it might be said that the average settler has \$1,000 to \$2,000 when he first sets foot on his land. He must spend some \$4,000 to \$6,000 before he is established and has a crop in prospect. Where is the money to come from?

Two bankers may be quoted. A Joint Stock Land Bank official, when the question was put whether it is easy for the reclamation farmer to get money for starting in, bluntly said no; that there is no security for a loan. The case is the same as that of a home builder who owns a lot and wants to build a house but has no money—the lot is no adequate security for the house loan. Building-loan systems have been worked out for the latter case, but no such system has been

established for the reclamation farmer. I asked a Federal Land banker, "Can a method of financing the reclamation farmer's start be worked out?" He answered, "I see no way in which it could be done"; but he did express himself hopefully about the method adopted by California—a state loan backed by retention of title and further secured by state supervision of its expenditure, which is not very far from a building-loan system.

Figures on the farmer's initial money requirements differ widely but a little generalizing may help to explain. He comes on a raw, uneveled and unfenced piece of land with a ditch leading water to one corner of it. He must build distributing ditches, which may cost \$10 to \$15 per acre; he must level his fields to receive the water and border them to retain it, at a cost of \$10 to \$100 an acre; he must spend \$2,000 to \$2,500 on fencing the land, building a house and barn, and buying stock and tools—and this is a low estimate. Finally he must plow and seed the land (another \$10 to \$40 per acre) and then sit down and feed his family while waiting for returns. The case is just the same on a Carey Act or district project; reclamation problems are not a particle different from irrigation problems on other projects.

For Delhi, Mr. Packard figures as follows: \$50 an acre for the distributing pipe; \$20 for leveling (this is a minimum estimate, and under the bad loose-sand conditions at Delhi is likely to be exceeded often); \$85 for buildings, water supply, etc.; a total of \$155 per acre—all this after the settler has bought the land at \$220 per acre! And the farmer makes his payments on all this money, *with interest*, and pays his water charges too. He pays or he gets out.

But to return to the reclamation project: Some money can be borrowed on the raw land, of course—at 10 per cent, a ruinous rate for fixed capital investment. The shrewd and hardy pioneer will do without usurious loans where possible, and manage by hook or crook to dig his way through the first year without much money to speak of. But this type of man is an exception, and it is hardly surprising under the circumstances if more men fail than pull through during the pioneer period. Yet many serious-minded people profess to regard the two to three crops of settlers as an indictment of reclamation, or of governmental awkwardness or something. Half a dozen farmers and irrigation managers have told me that they see no way of avoiding the three crops, and that the weeding-out process is inevitable.

California State-Aid Plan—On the California state settlements, the state finances the farmer's start, and it also requires that he must have money enough of his own to pay for 10 per cent of the cost of the land and 40 per cent of the improvements. The whole case is extremely interesting, but the point for the present is the result, as compared with reclamation results: At Delhi the settler has to invest very much more in the land than on any reclamation project, has to invest just as much in improvements, and has to repay in full, with 5 per cent interest running from the very first day; and practically 100 per cent of the farmers there manage to do this. The unfunded reclamation farmer, with much less to pay and with the interest on the cost of the irrigation works generously thrown off, fails in 50 per cent of the cases, and even where he survives he claims (or his loud-voiced representa-

tives claim) that he cannot pay the modest construction cost installments, *which are less than interest on the cost*. The comparison is not to the credit of the reclamation farmer; but it shows, among other things, that initial financing is a very important matter.

There is something to be said on the other side of the case. I have seen a number of reclamation farmers who started out with nothing and made a pronounced success—on the North Platte, Grand Valley, Minidoka, Umatilla, and Newlands projects, and probably they can be found on all. One of these farmers said, "A man who gets right down in the dirt and roots can't fail to make a success of irrigation farming here"; and he was one who had had no farming experience, being a former railroad carpenter. Genuine pioneering, in other words, still has its place.

Inflated Ideas of Pioneering—The oldtimers who went out into the Western forests and prairies to hew out a home did not generally start out with money, I believe, or get any extensive bank loans, but made a start somehow (though doubtless a lot of them failed, too). Irrigation farming is said to be harder than making a start in the woods, but the Mormon immigrants that finally reached the Great Salt Lake desert and irrigated it did not make a start with money, but very successfully starved themselves through the first year. Allowing for all the difference between former and modern conditions and needs, one is bound to give much weight to the opinions of long-time observers of irrigation conditions who say that one of the weaknesses of irrigation development is in the quality of the settlers, their inflated expectations, lack of readiness to endure hardships, and lack of instinct to help themselves and to win out. A Washington engineer attributes many irrigation failures to amateur settlers who "thought they only needed to tickle the soil to become rich, and when they found that they had to work two or three years they gave up."

Nevertheless, the settler's finance problem strikes me as very serious. The lack of reasonable credit discourages and pinches many who could otherwise make a successful start, and it loads up others with heavy interest charges that force them to plan their whole system for making money rather than making a living. It also leads to the loan company or banker becoming more important than the government or the project manager.

There are failures even under the Delhi system. But the failures are detected quickly (Delhi is less than three years old) and are weeded out promptly without the obstacle of ill-guided Congressional or Departmental mawkishness. The state is in the position of primary creditor and asserts itself; if a man is closed out it is the state that closes him out, and it does so before the state's equity has become impaired. On well-managed private or district projects something of the same kind happens. On federal reclamation projects the government never takes action to protect its lien or its equity but the loan creditor is always the one who closes the farmer out. So, very naturally, the mortgage or bank loan is the important obligation to the farmer, while the government obligation is unimportant—so unimportant that it really isn't there at all. As a private project manager told me, "We close out the failures promptly. The government can do the same thing; and it would, if it were left alone by the Secretary."

Project Management—As a matter of fact, the ordinary reclamation project may be compared to a \$5,000,000 to \$15,000,000 corporation doing a yearly business of several million dollars. The project manager is the executive head of this enterprise, and if he is supposed to develop the property and make it efficient he ought to have just the same freedom of action as the president of a manufacturing or commercial enterprise of the same size. But under the Department's practices the project manager has very little executive authority and is not expected to lead; he is powerless to prevent his farming community from going to the bad or to lead it on to improved methods of work.

This point is important because hardly any of the reclamation projects that I have seen or about which I have heard are up to a productive efficiency that might reasonably be expected of them. Since irrigation costs money, the land should be brought to high productivity, as against the very mediocre productivity shown by the crop figures which I reported last week. Many of the projects raise alfalfa as one of their main crops, and they ship it as hay, a low-grade crop, when they might feed it on the farm and ship milk and butter. Dairying is very inadequately developed on most projects, so farmers, business men and agricultural experts say. John F. Richardson, the Newlands project manager, who has worked specially hard to bring up dairying, says, "Every farmer that has good cows, tends to them decently and understands them, is getting along and paying his bills." And he explained that the project office and the experiment station there are constantly preaching the doctrine of "cow dung, elbow grease and butter fat" as the way to success.

Selecting the Settler—One interesting thing in the Delhi system is its wide difference from that by which reclamation projects are started up. At Twin Falls I heard a lively eye-witness story from a man who former lived in Billings, of how the Huntley reclamation project was opened with a grand land lottery. High officials of the Land Office were there from Washington—how on earth they butted their way into a reclamation proceeding I can not imagine—a little girl in a pink sash drew tickets out of a barrel, and lucky land-gamblers who never intended to farm got the first pick of the most valuable pieces of land, which they sold the same day at a huge profit. That barbarous method has not survived; moreover, under the conditions of the past few years there has been an automatic selection of settlers, for those who came were largely men anxious to build up a farm. But it still is true in all federal and in most private irrigation developments that the new settler is simply dumped on the land and allowed to wrestle with the severe problem of financing and the difficulties of a strange soil and country without the slightest help.

There is no provision in the reclamation law for financing the settler. It has even been decided by legal talent that the Reclamation Fund can not be used for giving the settlers advice. The results obtained on the projects, so far as I have been able to see, are fully as good as can be expected under these circumstances. All through, the project managers are in the difficult and uncomfortable position of being expected to develop their projects into successful farming communities by sheer faith and hope. They have performed brilliantly, even if they are engineers.

How Three American-Built Steel-Frame Structures in Japan's

Photographs Supplementing Report in Last Week's Issue by Wilbur S. Sample, Engineer

THE N. Y. K. BUILDING—No permanent distortion of the steel columns occurred but a large percentage of the masonry piers enclosing the exterior wall columns and the plastered partitions between the interior steel columns were shattered.

Capital Withstood the Violent Earthquake Shocks of Sept. 1

For the George A. Fuller Co. of the Orient, Which Built the Modern Structures in Tokyo

THE JAPAN OIL BUILDING—Steel frame proved adequate, the principal damage being identical with that in the N. Y. K. Building, noted on facing page.

THE MARUNOUCHI BUILDING—Another evidence of the stability of the modern structure. The main damage to masonry was below the fourth story. Reinforced-concrete floor slabs and interior walls stood up well

A Novel Type of Filter

BY GEORGE W. FULLER

Consulting Engineer, New York and Philadelphia

Abstract of a paper read Oct. 16, 1923, at Conference on Pollution of Streams by Industrial Wastes, Held at Engineers' Club, Philadelphia.

STREAM-LINE filters were one of the most interesting exhibits at the Shipping, Engineering and Machinery Exhibition at Olympia, London, in September. They are the [patented] invention of Dr. H. S. Hele-Shaw, last year President of the British Institution of Mechanical Engineers.

The principle of this filter was discovered last winter while experimenting with lantern projections to indicate the behavior of films under pressure in connection with the Theory of Stream-Line Motion, established by Dr. Hele-Shaw. Announcement of the discovery was made before the Royal Society May 10, 1923.

In its simplest form this filter is made of a pack of specially prepared paper, impervious to water and oil and somewhat roughened to provide passageways, the pack being held within a container between two pressheads. One of the pressheads is movable and provided with a screw arrangement for suitably compressing the many hundreds of sheets which make up the paper pack. Through the entire pack from presshead to presshead are two alternate sets of circular holes, the larger being for the influent and the smaller for the effluent. At one presshead are channels through which, under such pressure as desired, the influent is led to each of the openings of larger diameter; and at the other presshead are channels connecting with the smaller holes in order to remove the effluent. The influent, even under heavy pressure, can pass from the larger tubular openings only through the laminae of the heavily compacted pieces of paper, with stream-line motion, into the smaller tubular openings which form an exit from the filter.

These filters are built of the horizontal or vertical type. The largest stream-line filter exhibited at Olympia consisted of a battery of 16 vertical filters, each pack containing 16,000 sheets, 256,000 sheets in all, with 32 influent openings making "the total number of filter units 8,192,000." Its rated capacity was 10,000 gal. per hour.

Cleaning—Stream-line filters require frequent cleaning, depending upon the quantity and quality of influent filtered since the preceding cleaning. This is done in one or both of two ways: Either (1) the deposit on the walls of the influent tubular openings is pushed through suitable ports in the presshead by means of light free-fitting pistons which are actuated by the pressure normally used in forcing the influent through the filter; or (2) the deposit is removed by forcing the effluent back through the effluent openings, through the laminae of the compressed paper pack, thence through the walls of the influent tubular openings and out through a suitable port. I saw several packs of paper dismantled after more or less use in filtering various substances and I was impressed by the complete absence of stain or other sign of service by the paper, other than at the edges of the influent openings.

Accomplishments of edge filtration, as distinguished from ordinary filtration through a body of granular material, depend upon the ability to regulate the attenuation of the films in which the liquid passes in stream-line motion. It is essential that the material used in this new filter have a rough surface so as to provide passageways, as satisfactory results do not appear to be obtainable with smooth surfaces. The special paper now used is not only impervious and relatively cheap, but its flexibility allows pressure to be applied to the packs in varying degree, thus providing a control for the size of the passageways. As a result of passing certain mixed liquids through the stream-line filter several times, and increasing the pressure on the paper pack between each filtration, it is understood that different substances are removed each time, thus accomplishing what for convenience has been designated as "fractional filtration." The paper in use is said to withstand ordinary

acid solutions up to 10 per cent strength, but filtration is interfered with by alkalis approaching 1 per cent.

Some of the accomplishments of the new filter are as follows:

- Removes the color or stain from moorland swampy water.
- Produces a colorless effluent from a solution of erythrosin when diluted with 5,000,000 parts of water, and having a brilliant orange color with fluorescent green glint.
- Produces from milk a clear effluent, nearly tasteless.
- Extracts the oil from feed water.
- Separates water and impurities from oil.
- Extracts 30 per cent of the salt in sea water.
- Decolorizes unrefined sugar.
- Separates cyanogen from gas house sludge.
- Reduces dilute activated sludge to a 60 per cent water content.

It is too early, of course, to say much as to the economic worth of this filter in the industries or to outline the scope of its benefits to science. But the indications are that it will have a bright future along many lines of activity.

Armored Concrete Pavements in France

ISOLATED sections of concrete pavement strengthened against wear by embedded iron castings arranged symmetrically as illustrated, have been tried out successfully in a number of French cities. In constructing this pavement the base of lean concrete is leveled and smoothed with a coat of mortar on which the castings

CAST-IRON UNITS EMBEDDED IN CONCRETE PAVEMENT

are arranged by hand and then filled flush with a rich concrete. The castings, as illustrated, are about 2½ in. deep and weigh about 1½ lb. each. Their shape is such as to provide quite even distribution of metal in the surface of the concrete. There are about 25 castings per square yard. It is stated that wherever it has been tried this pavement has stood up remarkably well under heavy traffic.

Boating on Hetch Hetchy Reservoir

The completion of the Hetch Hetchy dam in the Yosemite National Park by the City and County of San Francisco for water supply purposes raised the question as to who had control of the renting of boating and other recreational facilities on the reservoir, which will be about seven miles long and have an average width of one-half mile. According to a decision rendered by John H. Edwards, solicitor of the Interior Department, a director of the National Park Service under the supervision of the Secretary of the Interior "has exclusive power to grant any concession affecting the Hetch Hetchy reservoir or the lands appurtenant thereto which will not in any way materially injure the structures of the reservoir, interfere with, or hinder the city's use of it, or in any way pollute the waters thereof."

Hints That Cut Cost and Time

For the Contractor and the Engineer

Simplifying the Taking of Soundings Under Adverse Conditions

By E. E. FAUNTLEROY

Engineering Department, Norfolk & Western Ry., Norfolk, Va.

TAKING soundings over a wide area, congested with shipping, where the water is deep and usually fairly rough, is a problem the solving of which may require considerable ingenuity. These obstacles are all encountered at the coal piers of the Norfolk and Western Ry. in the outer harbor at Norfolk, Va. Here a light wind makes navigation in the ordinary skiff uncomfortable; large steamers, tugs and small boats

the tide is unusually strong and the water 40 to 50 ft. deep. To mark points on the range lines a small floating target as shown in the sketch was effectively used, was easily made and could be quickly set and moved. These targets were set from 200 to 600 ft. apart as required and distances measured with a light wire 200 ft. long, using two boats with detachable motors. With this equipment and using fixed points on shore, the intersections of the range lines could be accurately located and the work done with despatch.

Moving 7,500-Ton Office Building to Provide for Street Extension

MOVING a seven-story office building of the Illinois Central R.R. at Chicago is one of the latest examples of the success with which large structures can be transferred from one site to another. The building is on the southeast corner of Michigan Ave. and Roosevelt Road (or 12th St.) and had to be moved 85 ft. south to permit of extending Roosevelt Road to the lake front. This structure, originally the Ashland Block, was torn down and rebuilt on its present site in 1890. It is about 130x80 ft. in plan, with its narrower side on Michigan Ave. and in the direction of travel. At the middle of the rear a court or recess reduces the width to 64 ft. The height is 100 ft. from street to top of parapet wall. Weighing 7,500 tons, it is said to be the heaviest building ever moved.

The building is of composite construction with exterior and interior brick walls, cast-iron columns, I-beam girders and wood joists. The outside walls and interior corridor walls are brick bearing walls, but in the two street fronts the walls do not extend below the ceiling of the first floor, being supported by cast-iron columns standing on stone piers whose tops were in the basement. Cast-iron interior columns in two sections of the building carry steel I-beam girders running lengthwise or east and west. Upon these I-beams are wood joists and wood flooring. Wood frame and composition covering constitute the roof. Originally the column spacing was about 17x20 ft., with the longer spacing north and south. A few years ago the east portion of the building was strengthened, on account of increased floor loading, by the addition of six intermediate cast-iron columns carrying I-beam girders and reducing the panel spacing to 17x10 ft.

Actual moving operations were limited to the period from 5 to 8 a.m. each week day, by order of the South Park Commissioners, so that traffic could be diverted from Michigan Ave. during the operations, such diversion being impracticable for the later heavy traffic on this congested thoroughfare. Moving was begun Sept. 24 and finished Oct. 3. Interior shoring was used only in the first-floor openings in bearing walls, to support the walls above these openings.

Although the distance moved was not great the work was made difficult by the small space available. Since the rear of the building in its new position is only 16 ft. from another structure there was no room for a straight

FLOATING TARGET FOR TAKING SOUNDINGS

are numerous, the tide is strong and water from 35 to 50 ft. deep.

Soundings are taken semi-annually. At right angles to the docks lines are run out at 50-ft. intervals and soundings taken on these lines at 10-ft. intervals up to 50 ft. out; thence every 25 ft. up to about 150 ft. out. The remaining area in front of and between docks, out to and across the channel, is divided into 100-ft. squares at the corners of which depths are measured. Along the docks a light graduated wire on a wooden reel for measuring distances out and a small rowboat serve admirably.

In the much used channel where there is more sea and where waves from passing steamers are bothersome, the problem is difficult. Here it is impossible to stretch a wire for any length of time, and a small boat must be quickly handled to prevent being run down;

pull with the hauling cables and these cables had to be led out to capstans placed in an open lot at the east side of the new site. Deadmen composed of steel rails were driven into the ground within the 16-ft. space and to these were shackled steel sheaves giving the cables a right-angle turn. Similar sheaves were shackled to heavy timbers under the building and bearing against the underpinning on which the building was carried. The cables were led to and fro under the building in the usual manner and the free ends were carried across the rear of the building to four two-horse capstans on the east side.

Timber blocking was built up in the usual way on the concrete floor of the basement and wedged tightly

MOVING 7-STORY OFFICE BUILDING IN CHICAGO

View looking west along Roosevelt Road. The building is being moved south for the widening of this thoroughfare. The tall tower in the distance, beyond the elevated railroad, is one of the connecting towers for the long Roosevelt Road viaduct, crossing railway tracks.

against the building, which was supported by needle beams resting on lines of stringers along both sides of the walls and columns. Several of these stringers were timbers 20x20 in. in section and 90 ft. long. Steel plates under each stringer rested on steel rollers riding on four lines of steel rails carried by the blocking timbers. Ordinary building jacks or screw jacks were used to take the load when separating the building from its foundations. After cutting the brick walls and cutting the cast-iron columns below the first floor level by means of torches, the building was ready to be moved. New concrete foundation walls and spread footings for the columns were built in advance on the new site, the walls being carried 3 ft. above basement floor.

In addition to the main movement to the south, the building had to be moved 6 in. westward to adapt it to the revised building line of Michigan Ave. This lateral movement was effected by placing the rollers at a slight angle across the lines of rails, so that for part of its travel the building moved diagonally or southwest. After the building reached its final position, a brick wall was built on top of the concrete wall between the large timbers and when the masonry had seasoned the weight was transferred to these piers by jacks, the timbers being then removed and the wall completed.

The moving of this large building was planned and directed by the Chicago Terminal Improvement organization of the Illinois Central R.R. of which Daniel J. Brumley is chief engineer. The work was carried out by W. H. Brown & Co., Chicago, with Hugo Filippi as engineer and superintendent in charge.

Hints that Cut Cost and Time

Pavement Warped by Adjustable Templet

BY PAUL L. FETHERSTON
Jackson, Michigan

AN ADJUSTABLE templet, similar to the one shown in the cut, can be used successfully in warping the surface of a concrete pavement. This templet can be made by placing a 2x4-in. timber over an ordinary split strike-off templet. The ends are raised from the templet by means of 4x4-in. blocks and securely bolted in place.

A center bolt is passed through both the templet and 2x4 and secured to the former by means of a nut. Wing nuts are placed on the bolt above and below the 2x4.

ADJUSTABLE TEMPLET FOR CONCRETE PAVEMENT

The camber of the templet should be about one-half of that required to produce a pavement surface of the normal crown. Then by depressing the wing nuts the 2x4 will be drawn down and the templet upward till the desired camber is produced.

On going into a superelevated curve or in any instance where it is desirable to alter or eliminate the pavement crown, the wing nuts are gradually turned upward as the templet is moved forward over the fresh concrete. The two members are thus forced apart and the camber of the strike-off is slowly eliminated.

This brace also serves to hold the templet rigid at all times so that its use insures a more even surface than can be obtained with an unbraced templet which tends to be slightly flexible.

Movable Derrick-Crane Economizes Space

BY DALE R. VAN HORN
Walton, Nebraska

UPON the site of the new Nebraska state capitol building are being used two specially-constructed traveling cranes, which are a combination of stiff-leg derrick and gantry crane. The cranes were built practically entirely on the job.

BUILT-UP CRANE ON NEBRASKA CAPITOL BUILDING

From Job and Office

For Contractor and Engineer

When material handling became an acute problem on the work, recourse to some sort of traveling crane with a long lifting radius was necessary. The usual gantry type, with distance between crane rails of 40 ft., could not be used because that spread between rails was not available. Also, space between rails had to be used to some extent for storage purposes. The stiff-leg derrick type was decided upon, but a type which allowed free movement to all parts of the job. Accordingly the crane herein pictured was built.

Deadweights to counteract the pull of the boom are provided on two sets of trucks loaded with stones and earth, and built up as timber cribbing. The weight of each deadweight is about 30 tons, and the distance between the two deadweights is 62 ft. This distance allows the hoisting engines to be set between the deadweights, thereby economizing space. The distance between crane rails is 26 ft. and the tracks are high enough so that a great deal of storage space for steel, timber and other materials is provided between tracks.

The boom of the crane is 106 ft. long. Inasmuch as the crane tracks entirely circle the site of the new structure, which is about 435 ft. square in plan, the cranes give a wide range of usefulness. The cranes are driven by 40-hp. steam engines.

Reclaiming Heavy Plate Girders

By J. C. LAMON

ON A LARGE hydro-electric construction job on the Little Tennessee River one of the railroad bridges was carried out in a flood. Owing to the difficulty of replacing the wrecked steelwork, it was decided to re-

claim the bridge. These huge steel girders—68 ft. in length and 6 ft. high, of heavy plate construction—though badly distorted, were reclaimed by ordinary blacksmith methods.

After the wrecked bridge had been hauled out of the water by powerful cranes, the girders were transported to a yard equipped with a 50-ton derrick and side-tracks. Heavy I-beams were laid at regular intervals, and the girders were placed on them with the mid-point of the sag in the girder directly over an I-beam. Then the girders were heated, slack coal, coke and crude oil being used. A long heat was taken at the apex of the sag; the heat was confined by packing slack coal on both top and bottom of the plate. Heavy pieces of coke

were placed on both sides of the narrow section of the girder, and with the aid of two powerful blow-torches with air pressure of 90 lb. a slow heat was taken. When the plates were sufficiently heated, the girder was allowed to sag of its own weight until straight at the particular point. This operation was repeated until the entire girder was gone over. The crane, with a sling, held the girder so that it would not be bent concavely. When straightened, it was blocked or jacked. At some stages of the work it was necessary to use both derrick and locomotive crane.

Flattening of the flanges and cover plates was accomplished by ramming with an iron rod 6 in. in diameter and 20 ft. long swung from the derrick.

Where the heats were taken, rivets were, of course, loosened, so they were cut out and new rivets were driven.

All-Year Railway Painting Program

THAT it is entirely practicable to arrange a railroad painting program covering the entire year, which will result in more efficient and economical work and will enable the railroads to retain their best men as a permanent force, is the conclusion of a committee which reported at the recent annual convention of the American Railway Bridge and Building Association. An abstract of the report is given below.

The general understanding has always prevailed that railroad buildings, bridges and other structures should be painted only during the summer months and therefore it is established practice to organize painting crews in the spring and disband them in the fall. Thus each year the railroads face the problem of finding new painters and in most cases must take on new and inexperienced men and train them. In a measure the railroads become the training school for the local contractors and lose much in economy and quality of work.

The question is: Can a program of work be so planned as to give painters work all the year round? The answer as developed by the investigations of this committee is in the

PLATE GIRDERS BEFORE AND AFTER STRAIGHTENING

claim the bridge. These huge steel girders—68 ft. in length and 6 ft. high, of heavy plate construction—though badly distorted, were reclaimed by ordinary blacksmith methods.

After the wrecked bridge had been hauled out of the water by powerful cranes, the girders were transported to a yard equipped with a 50-ton derrick and side-tracks. Heavy I-beams were laid at regular intervals, and the girders were placed on them with the mid-point of the sag in the girder directly over an I-beam. Then the girders were heated, slack coal, coke and crude oil being used. A long heat was taken at the apex of the sag; the heat was confined by packing slack coal on both top and bottom of the plate. Heavy pieces of coke

affirmative, and it is being done successfully on some railroads. Outdoor painting can only be done when weather conditions are favorable, but such work as can be protected from the weather or is indoors may be done at any time.

Painting steel bridges is, for the most part, limited to the months of June to September, inclusive, although further south this period is extended. The painting of other steel structures such as tanks, turntables and signal bridges is also limited to about the same period, but the season for painting wooden buildings and structures is somewhat longer as the work may be done both earlier and later in the year. The remainder of the year may well be named the indoor season, and during that period any class of interior painting or the painting of objects that may be brought under shelter may be done. It may be well to note the practice on the Grand Trunk System, as reported by

George A. Mitchell, Superintendent of Bridges and Buildings:

"The practice which has been in force on my territory (something over 2,000 miles) for a number of years has enabled me to maintain a regular force of painters during the entire year. During June, July, August and September our painters are wholly employed in painting steel bridges. During April, May, October and November, and some seasons the fore part of December, they are employed in the exterior painting of buildings. The balance of the time they are employed in painting and decorating the interiors of our buildings. Therefore the work is so distributed in this northern country that we are able to employ our painters the entire year and consequently we have men in our service for many years who become accustomed to and skilled in our particular work."

A painting program could be outlined which would permit the employment of an average crew on a division during the entire year, with the addition of a few men during the outdoor season when there is an unusual amount of bridge painting to be done. The painting crew is equipped with light rigging, easily handled, that will save the expense of building scaffolding and enable the men to make many minor repairs.

Another feature worthy of serious consideration is that painters are good mechanics and are capable of doing other work more economically than crews sent specially for that purpose. For instance, a painting crew working at a station could replace broken glass, take down stove pipes in the spring and clean, paint and store them. They could clean out gutters and conductor pipes and paint them before they begin to rust. In the fall they could take out window screens, clean and paint them, and put them away.

Renewing Railroad Culverts

REBUILDING old culverts, putting in new drain pipes and culverts and replacing old box culverts with pipes is a class of work continually required in railway maintenance, and the following particulars of such work are abstracted from a report of the American Railway Bridge and Building Association:

Trenching—In unstable soil where a temporary opening must be made in the fill, pile bents may have to be driven, sheeting being placed behind them to support the sides of the trench. Piling should be driven only when absolutely necessary, on account of the increased cost.

Where an open trench is used for small pipe it is advisable to transfer the track support to some distance on each side of the trench. One method is to place a 6-ft. length of second-hand bridge stringers flatwise under the ties, under each rail. The trench should also be cross-braced with trench jacks. The Pennsylvania R.R. places a track rail under the ends of the ties, with the head up, and immediately over it another rail on top of the ties, fastening the two rails together with clamps. This provides a strong support at minimum expense, as extra rails are usually available. Where ties are not supported on account of trench excavation, the Illinois Central R.R. places a rail on each side of the traffic rail with hangers that pass under the latter rail and over the extra rails.

If the pipe is large or if two or more pipes are placed side by side, an approved method is to dig a narrow trench under the track at each end of the section to be excavated, set up frame bents and support the track on stringers placed under the track ties. This is a good method to use when removing old or broken culverts.

Tunneling—When the height of the embankment is too great for an open trench it is necessary to drive a tunnel, or the trench method can be used for the ends and the tunnel for the portion under the tracks. One method is to excavate carefully to the proper dimension and place timber or plank sets as the excavation proceeds, placing the mud sill and top first and while holding the top in place with a jack, place the side pieces, after which a strip should be spiked to the top piece to keep the sides from crowding in. Another method is to excavate 3 or 4 ft. wide, set up frame

From Job and Office Hints that Cut Cost and Time

bents and drive lagging over the top of the bents. As only a small force can be worked in a tunnel it is advisable to work from both ends. Tunnel work can be handled best during the winter season. Where small pipe lines pass under several tracks, it is often advisable to sink shafts between the tracks and tunnel under the track between the shafts. If the ground is firm it is often possible to tunnel between shafts without using any supports if the pipe can be placed at once and the backfilling is tamped into place.

Boring and Jetting—On the Southern Pacific Ry. water and gas pipes up to 3-in. in diam. are tunneled through earth embankments with a dirt auger and if sufficient water pressure is available they are jetted through in the same manner as jetting piles.

Chicago, Milwaukee & St. Paul Ry.—We are placing 24 to 48-in. concrete pipe inside of timber culverts 36 to 300 ft. long under fills 6 to 125 ft. in height. Regardless of the size or length of pipe, we slide it into the culvert on a skidway that extends all the way through, and far enough outside to enable the pipe to be rolled onto it. The skidway is made of 2x4 or 2x6-in. timbers with chamfered edge, laid 8 in. apart for 48 in. pipe and a little closer for smaller pipe. The skids, spiked to the bottom timbers of the culvert. They are well greased in warm weather, and in freezing weather they are made wet to form ice. For pipe with bell ends a hardwood shoe is placed under the spigot end to raise it level with the bell end so as to prevent the sharp edges of the pipe from cutting into the skids. Except for the largest pipes we seldom use block and falls as the pipe moves easily on the greased skids. With a crew of eight men we average 50 to 60 ft. of 42-in. pipe, placed, backfilled and tamped per 8-hour day. We haul the backfilling material in a box on runners made to fit the skidway.—T. E. McFadden, Cedar Falls, Wash.

New York, New Haven & Hartford R.R.—We recently renewed a culvert under a single track section over which 29 trains operate per day, located about 3-mile from the nearest siding where a work train was enabled to clear regular trains. The fill is about 10 ft. high. The culvert carries a small brook and tidewater which interfered considerably with the progress of the work. As the fill was of granite riprap, piles could not be driven; therefore the track was supported by 3-ply 15-in. I-beams 24 ft. long under each rail, which in turn were supported by four 12x12-in. hard pine underlays.

The stone fill was cut by means of hand drills and wedges, and the sides of the excavation braced as the excavation proceeded until a depth of about 11 ft. below base of rail was reached. When the excavation was completed the I-beams were removed and five lengths of concrete pipe were installed by use of a derrick car. Then a sufficient backfill was made to carry the track. This work was done between midnight and 5 a.m. as this was the longest period in the 24 hours during which the track was unused.—E. E. Candee, Waterbury, Conn.

New York Central R.R.—A small stone box culvert which had failed, was replaced with a 42-in. cast iron pipe culvert, 156 ft. long, and 31 ft. deep, under four main tracks. It was necessary to take out the stone of the old culvert, and tunnel through the bank, using 8x8-in. timber frames for a tunnel 5 ft. square. After the tunnel was completed, we put in the first near the middle and backfilled over it, ramming the material in tight. Then, another pipe was drawn in from each end, and connected to the first pipe and material backfilled over each of them, and rammed tight, so that we had a tight culvert, with no place for water to run through outside of the pipe and cause trouble.—R. H. Reid, Cleveland, Ohio.

Delaware, Lackawanna & Western R.R.—We had to renew a timber culvert carrying a double track passenger

From Job and Office

For Contractor and Engineer

line over three pipe lines supplying water to Jersey City. The pipe lines consisted of 36- and 24-in. cast iron mains and an old 30-in. brick conduit, all supported on timber grillage on piles. The tracks carried about 150 movements in 24 hours. The soil was 12 ft. of black mud over clay subsoil. The pipes were about 2 ft. apart and the top of the brick conduit was not more than 18 in. below base of rail. A highway prevented track diversion on the east side and a steel viaduct carrying an electric line over the railroad prevented a double track diversion on the other side. Further there was not space above the pipes to support the track on falsework and leave room for the new reinforced concrete slab.

It was necessary to locate a single track detour for west-bound trains and carry the eastbound traffic on a gauntlet track laid on the same ties, thus avoiding the throwing of switches. Train movements were protected by flagmen at each end of the detour with hand-operated home and distant signals. This arrangement permitted the old track to be used in driving the piles to support the new structure and for unloading concrete material. It also resulted in a minimum delay to trains.—F. L. Wheaton, Buffalo, N. Y.

Job and Office Notes

Further Experiments With Rubber Paving Blocks are being carried out in Britain. A street in Manchester is being paved with rubber, the traffic passing over it daily being around 9,000 vehicles and some 1,000 trams; the total weight being estimated at 15,000 tons. Instead of the usual method of employing small blocks as in wood paving, large slabs of rubber weighing 600 lb. each will be used. The slabs are reinforced by steel bars in order to prevent the creeping of the rubber, and each slab is secured to the next by steel pins. Creeping is one of the troubles to which rubber roadways are liable. As showing the extent to which they can be moved it may be said that a five-ton vehicle passing over a surface of rubber blocks will spread them half an inch. The slabs will be laid on a concrete foundation, to which they will be attached by a bituminous compound which is impervious to water. The surface of the slabs are corrugated, to give the appearance of small blocks, and thus affords a safe foothold for horses. In addition, the slabs are reinforced at intervals with steel bars, which keep them rigid while retaining the necessary pliability to insure noiselessness.

Inspection of the Formula for Solving vertical curves given in *Engineering News-Record*, Sept. 13, p. 443, "indicated the familiar parabola," writes H. S. Martin, of Cope Rand Means Co., Engineers, San Francisco. "I computed the point of elevations for the complete curve by the method outlined," he continues.

"The result was a series of point elevations that bore no resemblance to a vertical curve connecting two tangents, and when plotted, a line drawn through them crossed the forward tangent produced between 11 + 50 and 11 + 75 and got back to 12 + 50 only by exceeding the grade of the following tangent for the last two chords. I then extended the forward tangent back to 10 + 00 which gave a new value to D of 5 ft. instead of 7.5 ft. Computing in the reverse direction I obtained an entirely new series of point elevations, equally in error but not so conspicuous when plotted. The fault, however, does not lie in the formula but in the application, or at least in the apparent assumption that it can be applied to locations having unequal tangent distances. If the curve is properly located, i.e., with the P.C. and P.T. established at points equidistant

from the grade vertex, the formula will give a true parabola from either tangent. In the example illustrated D would have its true value of 6.25 ft. for a curve of 250 ft. long and of course be the same from either tangent. I see no advantage in the given formula for working from one tangent over the essentially same one from both tangents. Errors in numerical work are not easily discerned in either. For universal application I prefer to establish the P.C. and P.T. elevations from the tangents and then compute from one to the other along the curve, for the chord points, by the rate of grade change method and thereby secure a check on the computations. This is also, I believe, the least tedious method when grade rates and elevations have several decimals; conditions very frequent in rectification of grade work."

Liquid Oxygen Explosive Has Been Successfully Used in Colorado by the Department of the Interior in experimental mine blasting and road construction work at a cost of approximately one-half that of the gelatin dynamite required to do the same work. The experiments were conducted by E. D. Gardner, mining engineer of the Bureau of Mines, in co-operation with a representative of the Compressed Air Corp. A liquid oxygen explosive consists of gas black, wood pulp or some other carbonaceous material made up into cartridges and soaked in liquid oxygen. This explosive can be detonated similar to ordinary dynamite with cap and fuse or with electric detonators. The liquid oxygen was obtained from a plant designed to furnish oxygen gas and was shipped to the point of use in dewar flasks, which are made on the same principle as thermos bottles. The first Colorado tests made by the Bureau of Mines were conducted with cartridges made in Germany, but later cartridges manufactured at less cost in Denver proved very much more satisfactory. As the use of this explosive is new in this country, numerous tests and experiments were necessary to find a low-priced carbonaceous material which would have the desired qualities and to learn the technique of blasting with this new material. Hand steel holes were blasted in granite on a road construction job above Idaho Springs, with results similar to those obtained with 40 per cent gelatin dynamite. Trees were also cleared from the right-of-way and a 200-ton cliff blasted down successfully. Instantaneous electric detonators and blasting battery were used for this work and no misfires occurred and no holes failed. Disregarding express charges on the oxygen, the cost of liquid oxygen was about half that of gelatin dynamite.

It is Almost an Axiom Among Paving Contractors that industrial outfits are not adapted to grades in excess of 4 per cent, and frequently contractors owning industrial outfits have been unable to bid on work due to the existence of steep grades. C. M. Hathaway, engineer of construction, Illinois Division of Highways, Springfield, Illinois, recalls one instance wherein a contractor operated his industrial outfit on a "down grade" of 6 per cent for a distance of about 1,000 ft., this grade being located a short distance from the unloading plant so that all trains were compelled to make the grade while loaded. In this instance the contractor had suffered a wreck on account of his train running away, whereupon he contrived a rather novel device to protect himself from further accidents. An ordinary block pulley was installed at the top of the hill and held in place by means of a deadman anchored in the roadside, and a wire cable running through the pulley was attached to the rear end of the train descending the hill. The other end of the cable was attached to a motor truck at the foot of the hill and as the loaded train descended, the truck was automatically drawn up, acting in the nature of a counterweight. At the same time the operator of the truck kept his engine running in order that he might produce additional resistance by throwing his engine in gear, if necessary. The scheme was very simple and effective, and in addition the truck pulled the cable back to the top of the hill for another train load as soon as disconnected from the descending train.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Earth Dams Require Study

Sir—The failure of the Apishapa Dam, concerning which there has been considerable comment in recent numbers of *Engineering News-Record*, may not have been in vain if it results in the giving of more attention to a careful selection and study of materials to be used in earth embankments.

You have already favored me by publishing in your issue of March 1, 1923, a brief reference to work which the Division of Agricultural Engineering of the U. S. Bureau of Public Roads has been endeavoring to undertake. I say "endeavoring," because the co-operation that has materialized from engineers generally up to the present time, excepting the engineers of the U. S. Reclamation Service, has been very disappointing, only two or three even expressing any material interest in the subject.

It is interesting to note that practically every engineer constructing earth dams who has replied to letters addressed to him upon the subject has taken the position that the dam which he himself was constructing was so well designed that there could be no doubt as to its absolute security and it was therefore unnecessary to make further investigations, possibly forgetting that data regarding the perfect dam are the data most desired. It is also interesting to note in this connection the fact that no two of such dams referred to have been even closely similar in design. In no instance that has been called to my attention, moreover, has any critical study been reported to me as having been made of the soluble matter contained in the soils, the best and most efficient moisture capacities of the soils, the expansion or shrinking of the soils when exposed to alternate saturation and drying out under normal storage conditions, the most effective mixture of earth materials available in a given locality, or of a number of other studies that ought to be made in so important a matter; nor has any provision been made, so far as I am informed, for a study of percolation through, or of the hydraulic pressure under, any earth dams that have been built recently or are to be built in the near future, excepting in one instance.

A long experience with and rather careful study of the problems involved demonstrates to me that even in connection with minor structures, such as backfilling earth for headgates, flume ends, and in the construction of small dams as well as large ones, different soils must be treated in very different ways. Some soils must be thoroughly saturated and rammed into place, practically puddled, while others are most satisfactory with what is known in soil studies as the field carrying capacity of moisture. It is such studies as these that it was, and still is, although somewhat less optimistically, hoped that the Division of Agricultural Engineering, as referred to above, might be able to study in detail.

Permit me to direct your attention to a very valuable article on this subject, written by Dr. Alex L. DuToit, geologist, entitled "Some Experiments Upon the Contractions of Soils in Application to Earthen Dams," which appeared in the July, 1923, number (Vol. 2, No. 3) of the South African Irrigation Department Magazine. The author calls particular attention to the complicated nature of the questions that may arise in excessive wetting, and the subsequent shrinkage, of soils, particularly those of a clayey nature, and gives us the results of some investigations that have been made in the West Indies, on a limited scale.

So far as I have been able to discover in studying the

details of construction of the Apishapa Dam, no careful studies were made at any time of the proportion of soluble elements contained in the soil, of its optimum moisture content, of either the co-efficient of expansion or shrinkage under varying conditions, or by making of any analysis, either chemical or physical, to determine what, if any, commingling of the soils to be used was needed. In the construction of a concrete or masonry dam, the cement, the sand, the gravel and the water, and combinations of these ingredients of the concrete, are studied with the utmost care. Such study is fully as important, perhaps even more so, in the study of the earthy materials of which it is planned that a dam shall be composed. The fundamental trouble is that in the construction of a masonry dam, the fact is recognized that an experienced engineer, reasonably well paid, should have charge, but in the case of an earth dam it is assumed that any one who can run a level is competent to direct, whether he has ever before had anything to do with such a structure or not.

It is my opinion also, based upon my study of a number of earth dams that have failed, and also of many dams showing no signs of failure, that no dam, the failure of which could in any way endanger the public safety or welfare, should be permitted to be constructed without requiring that all possible safeguards, such as have been mentioned herein, be thrown around it by those in authority.

A. LINCOLN FELLOWS,
Senior Irrigation Engineer,
U. S. Department of Agriculture.

Action of Frost on Foundations

Sir—I have seen your article "Action of Frost in Heaving Concrete Piers" in *Engineering News-Record* for Aug. 30, 1923, p. 360, wherein is described one of the many cases in which frost has shown its bad influence on engineering works.

It may be of interest to you and some of your readers to hear that in Sweden, and especially in its northern parts, where the frost penetrates one or two meters in the ground, we insulate almost all foundations of houses, retaining walls,

etc., by means of such materials as steam coal ashes, peat and so on, which have small capillarity and heat conducting power. In this way it is possible to avoid the heaving of subsoils which are sensitive to frost. Without such precautions the water-soaked earth filling will adhere strongly to the foundations, as if the whole were one solid block, which would irresistibly follow the physical law that frozen water takes greater volume than unfrozen. If such an insulation had been arranged around the described pier and an ordinary drain had been laid down at the bottom, the heaving should never have occurred.

The sketch shows the method of insulating the foundation of a house in northern Sweden.

If you are interested in the above question I may also refer to my report, No. 8, at the international highway congress in Seville this spring, in which report I have tried to treat the question of the influence of frost on the highways. There you will also find some notices about our insulations of the railway tracks in northern Sweden.

In reference to the intricate question of highway construction I am almost convinced that it will not be brought to a satisfactory conclusion until we highway engineers have succeeded in deeply penetrating the secrets of the frost action.

Stockholm, Sweden,
Sept. 20, 1923

GUSTAV DAHLBERG,
Civil Engineer

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

A Civil Engineer Degree at the Age of 81 years was the unusual record of Frank L. Weaver, who in 1871 found it necessary to leave the engineering class of the University of Kansas and go to work and who in 1922 went back and took up his unfinished course with the result that on Oct. 1, 1923, he won the degree of B. S. in civil engineering from that institution.

Canadian Road Construction Expenditures of \$15,000,000 are reported for this year's season ending Nov. 15, the Dominion government contributing 40 per cent of this. Up to the end of April last a total of \$11,350,000 of the \$20,000,000 federal highway grant had been paid out, and this year's payments will be about \$4,000,000 additional.

Preliminary Work Is Being Rushed on the Island Falls power project of the Hollinger Consolidated at Timmins, Ontario. The work will require a spur line from the northerly extension of the Temiskaming and Northern Ontario Ry. Contractors are already engaged in clearing the right-of-way and clearing the site preparatory to the commencement of excavation.

Work on the Power Structures at Muscle Shoals is 60 per cent complete. Due to the favorable season, great progress was made during September and October. On Nov. 1, 630,000 cu. yd. of the concrete work had been completed. In all, 1,300,000 yd. of concrete must go in. While only half of the concrete work has been done, the job is more than 50 per cent complete since all the cofferdams are in, all of the plant installed and all of the construction buildings completed.

Electrification of the State Railroad between Stockholm and Goteburg is to be undertaken at an estimated cost of 6,000,000 crowns (\$1,578,000). The Swedish State Railways estimate the amount needed for new construction work during the ensuing fiscal year at 15,800,000 crowns (\$4,154,400) which includes the electrification project and also includes expenses for a number of operations for which funds already have been appropriated. The amount of new appropriations needed is about 9,000,000 crowns (\$2,367,000).

Repair Work on the 100 Miles of the Alaska Railroad damaged by high tide and heavy storms that put the line out of commission has proceeded to such an extent that traffic has now been resumed. The two large bridges that were washed away near Spencer Glacier and Bartlett Glacier have been replaced by temporary pile bridges and the washed-out embankments and cave-ins have been reconstructed. In order to prevent the congestion of freight due to the suspension and delay of traffic a regular weekly boat schedule to Anchorage has been arranged.

U. S. Reclamation Service Further "Reorganized"

A new order by Secretary of the Interior Work on Nov. 6 changes the administrative system of the Bureau of Reclamation (the former Reclamation Service) by removing the operation of the projects from engineering direction. After Dec. 1 the chief engineer of the bureau is to confine the work of his office to investigation of proposed projects, design and construction, while operation and management of the projects is to be in the hands of a field commissioner. The present field commissioner is Miles Cannon, a politician. F. E. Weymouth is chief engineer. Statements given out by the department claim that the change with the elimination of an assistant commissioner and the assignment of the photographic laboratory to the Geological Survey will save \$10,000 a year in salaries.

New Railroad Across the Niagara River

The American Niagara Railroad Corp. has been authorized by the Interstate Commerce Commission to construct 10.36 miles of track from a connection with the New York Central in Tonawanda to the international boundary where it will connect with the Canadian Niagara Bridge Co. which has been authorized by the Canadian government to construct a line from the international boundary to connect with the Canadian Pacific Ry. The cost of the new line, including the double-track main line and yards, is estimated at \$18,000,000. It is to be owned jointly by the New York Central Railroad Co. and the Canadian Pacific Railway Co., the New York Central holding the majority of the stock.

Denver Water-Works Program of Construction

Plans for the following major improvements provided for in the recent bond issue are being prepared by the engineering department of the Denver Board of Water Commissioners: Relining and covering Ashland reservoirs, \$100,000; building a 66-in. conduit from Marston Lake to the city, \$840,000; constructing filters on the north side of Marston Lake, \$1,250,000; extension of a 60-in. pipe line from Kassler to Marston, \$750,000; extension of a 54-in. pipe line from Massey Hill to Wynetka, \$450,000; increasing the efficiency of the slow-sand filters at Kassler, \$500,000; total, \$3,890,000.

Late in October the board authorized additional large distributing mains in the city estimated to cost nearly \$750,000. Work on these mains will proceed with all possible speed, according to an official bulletin of the board.

Earning accounts for 1922 totaled \$1,906,375. Operating and maintenance expense was \$755,827, and interest on bonds was \$639,799 leaving a balance in net income of \$510,749 expended in capital improvements and extensions.

Sewage Plant Operators of Iowa Discuss Problems

Operation and Maintenance of Septic and Imhoff Tanks, Filters, Pumps and Siphons

More than fifty sewerage-works operators and others interested attended the fifth conference of Iowa operators on sewage treatment problems held Oct. 22 to 24 at Iowa State College, Ames. Septic tanks, Imhoff tanks, sand and sprinkling filters, each came in for a session with special papers on siphons, pumping stations and sludge handling. After a subject had been presented by a series of papers, C. H. Currie, consulting engineer, conducted a question-and-answer discussion.

H. V. Pedersen, state sanitary engineer, opened the conference with a statement of the present status of stream pollution and efforts to abate it by the 191 plants in the state, serving a population of 325,000. About 30 per cent of the domestic sewage of the towns having sewerage systems is treated to a non-putrescible state. Aside from the Des Moines and Cedar Rivers the rivers within the state are short and small. They are so polluted as to make bathing dangerous and fish life impossible. Mr. Pedersen held (1) that there is a growing sentiment demanding that streams be kept fit for bathing, (2) that to do this "finite limits of pollution must be set, (3) that public opinion must back up the department entrusted with the duty of setting the limits and seeing that they are not exceeded and (4) that the Legislature must provide the necessary organization within the State Board of Health.

Following this paper J. J. Hinman, Jr., chief of the water laboratory division, Iowa State Board of Health, indicated the relation of sewage treatment to water supply.

SEPTIC TANK PROBLEM

Prof. C. S. Nichols, Iowa State College, presented the septic tank problem, giving first a resume of its history, design limits and what a tank is supposed to do. He emphasized the point that any tank is only a preliminary process as it can be expected to handle but one-third of the soluble organic matter which is usually but one-half of the total amount, the remainder being solid matter.

Prof. Earle L. Waterman, Iowa State University, in his treatment of Imhoff tank practice, stated that there were 6 Imhoff plants in Iowa and 80 per cent of all those being designed were of the two-story type. After noting design features he gave a schedule of operations which include (1) daily cleaning of screens and grit chambers, (2) weekly cleaning of sides and bottoms of settling chambers, (3) removing floating material from settling chamber, to prevent septic action, (4) equalizing sludge deposits, (5) breaking up scum on gas vents, (6) observing depth of sludge, drawing and drying it. Difficulties arising from inefficient operation

are septic action in settling chambers, clogging of slots and sludge pipes and foaming at gas vents. If the schedule is followed Prof. Waterman held that the troubles would be largely eliminated.

Stanley Pincel, Engineering Extension Department, Iowa State College, in discussing the disposal of sludge, was optimistic as to its use for fertilizer by farmers. One operator indicated that he had no difficulty in getting Imhoff sludge taken away and contemplated making a minimum charge which he thought would make the sludge even more sought after.

Dr. Max Levine, Iowa State College, has been working on creamery wastes and finds that they can be handled by the activated-sludge process but it requires 50 to 60 cu.ft. of air per gallon and 6 to 12 hours' time. This, however, is not impracticable for the amounts are usually not large. An operator of a much-complained-of creamery plant at Sioux Center outlined his troubles. Undoubtedly he will soon be blowing air through his wastes, thus benefiting directly from the conference which brought the results of experiments to him.

Lafayette Higgins, consulting engineer, outlined trickling filter practice, largely by a description of the two-year old plant at Indianola. Major Edward D. Rich, chief engineer, Michigan State Board of Health, did the same for sand filters by a résumé of the operation of plants in Michigan. Aside from private plants for institutions there are 31 sewerage-works of all kinds in Michigan, the present status and operation of most of which were described by Major Rich. Cultivation or hand raking to overcome clogging of sand filters seems to be standard practice.

The last day's program consisted of a laboratory demonstration of ordinary plant tests and an inspection of the treatment plants for the college and town.

"Design, Operation and Care of Pumping Stations" was the title of a paper by C. S. Timanus, with Burns & McDonnell, consulting engineers. L. E. Rein, of the Pacific Flush Tank Co. in his talk on siphon troubles, said 90 per cent of them were due to air leakage. Soap and a shaving brush were the handiest tools to test for leaks.

Ten North Carolina Road Contracts Let

On Oct. 10 the North Carolina State Highway Commission let contracts for ten projects, upon which 97 bids were submitted; the projects comprising three bridges and seven road jobs. There were 57.02 miles of roads let, costing with the bridges included, \$1,336,582, exclusive of the usual 10 per cent for engineering and contingencies. Of this mileage, 19.9 miles were of standard concrete surface, and the average cost per mile was \$33,406.53 which included grading, draining, paving, reinforced-concrete bridges and culverts and all other items of construction; 73 miles of this pavement were 18 ft. wide and the remainder was 16 ft. in width. Of the remaining mileage 37.12 miles were of earth, or topsoil construction and cost \$11,005 per mile. The bridges and culverts cost \$433,364 of which one bridge over the Cape Fear River cost \$204,201.

Birdseye Party Successfully Surveys Grand Canyon

Col. C. H. Birdseye, chief topographical engineer of the U. S. Geological Survey, who led a party of engineers reported in distress while making a survey of the Colorado River, at a luncheon given Oct. 29 in Denver by the Denver chapter of the Colorado Society of Engineers, described the survey trip as follows:

"We knew nothing of the worry of the outside world, until we reached Diamond Creek Oct. 3. Here we were handed copies of newspapers and saw that the whole thing had been greatly exaggerated. We never had a boat bearing the initials U. S. G. S., therefore we cannot say anything about the empty boat found floating bearing those initials. On Sept. 19, the night the flood started, the party was camped just above Lava Falls in the Grand

All Because of a Broken Main

THE photograph herewith shows what happened when a water main, under heavy pressure, broke in Wilmington, North Carolina. M'Kean Maffitt, superintendent of public works, sends in the picture with these words: Broken water main under 100 lb. pressure; a washout; a Ford; a splash; no damage.

Canyon. We were forced to move camp several times, the water rising 18 in. an hour, the total rise in the 24 hours being 21 ft."

The trip consisted of 455 miles. There were four boats in the party, and when the water was at flood stage they made between 35 and 40 miles a day. Twenty-five rapids were encountered in Marble Canyon, while ninety rapids of major size were found in the Grand Canyon proper. Previous to the flood the party was in touch with the outside world, by wireless, the principal points heard were Los Angeles, Denver, Colorado Springs and Chicago.

Regretting the worry caused, Colonel Birdseye admitted that while so many were worried the party was peacefully at work making the necessary surveys. The work started at Lees Ferry, Ariz., in August.

Failure of Morris Canal Bridge Caused by Collision

Further investigation into the cause of the failure of the Morris Canal bridge at Garrison Ave., Jersey City, N. J., reported in *Engineering News-Record*, Oct. 11, 1923, p. 614, has revealed that thirty-five minutes before the bridge collapsed under a truck which with its load weighed over 14½ tons (the load limit was plainly marked as 8 tons), another truck had collided with the end post of the center truss, damaging both it and the truck.

The end post was of cast iron, octagonal in section, its lower end encased in masonry close to the edge of the bridge seat, and its upper end forming a cap on which the main shoe of the truss rested. The truss apparently was not bolted or fastened to the end post in any way so that in case the end post received a heavy side blow the support of the truss would be destroyed. All evidence points to this as being exactly what happened; the first collision damaging the bridge up to the point of failure.

The time of the accident was at noon on October 2 and not at midnight as previously stated.

New Joint Sewer District Formed in Los Angeles County

More than a dozen towns and small cities in southern California, between Los Angeles and the ocean, are planning to obtain an adequate sewerage system through the formation of the South Central Metropolitan Sewer District. A large number of property owners have signed a petition calling upon the county supervisors to create a sanitation district for the area involved, under the provisions of Assembly Bill No. 191 passed at the last session of the legislature.

This act authorizes the formation of certain joint sewerage districts and the issuance of district bonds under the direction of a board of directors composed of the mayors of each city involved, and at least one county supervisor, which board has authority to employ engineers.

In the district involved sewer systems serve less than one-third the present population and the move underway has two primary objectives, namely, "(1) to protect public health from cesspool conditions which are rapidly becoming alarmingly serious and (2) to prepare the district for a large increase of population."

On the basis of cost alone, it is stated in literature urging the move, the sewerage plan is justified because the "30,000 active cesspools represent an annual outlay [operating expense?] of \$500,000 which would retire the interest and sinking fund on an investment of over \$8,600,000. Such an amount would more than pay for a comprehensive sewer system to say nothing of saving vast sums in the future."

After a hearing before the board of supervisors the next procedure would be the organization of a board of directors and finally the holding of a bond election. The district as now being formed includes Compton, Watts, Willowbrook, Huntington Park, Maywood, Monterey Park and other communities.

North Jersey Moves for Joint Water Supply

Wanaque-Ramapo Development of 150 m.g.d. May Be Required—Talk of Buying All Private Companies

At a hearing held by the North Jersey District Water Supply Commission at Newark on Nov. 1, the fact was brought out that applications in hand and in sight for a share in the Wanaque water development now being carried out by the commission, will absorb the entire safe yield of that stream within a few years and that in addition other communities that are now turning toward the commission to invoke its services in providing for their future water needs will make it desirable, if not imperative, for the commission to develop a second source of supply. Present indications point to the Ramapo as this second source, especially since Bayonne, which had been granted a right of 50 m.g.d. in the Ramapo by the State Board of Conservation and Development, was recently enjoined from carrying out this plan because the courts held that approval of the North Jersey District Water Supply Commission as well as of the State Board of Conservation and Development was essential.

The hearing developed the fact that, acting upon the advice of Robert Spurr Weston, consulting sanitary expert, Boston, Mass., the city authorities of Bayonne would probably apply to the North Jersey District Water Supply Commission within a short time for 20 m.g.d. with the understanding that the Ramapo source would be developed as well as Wanaque. It appears that the safe yield from the two collecting areas would be at least 100 m.g.d. and 50 m.g.d., respectively.

WANAQUE DEVELOPMENT

After joint negotiations between Newark and some of the other municipalities to the north looking toward the filing of applications with the North Jersey District Water Supply Commission for the development of the Wanaque, some time back had come to nothing, the city of Newark alone applied to the commission for this development up to 50 m.g.d. As a result, the Wanaque Dam has been under construction for some time past, with foundations sufficient for raising the dam to store the entire yield of the stream, and work has been started on a conduit therefrom to Newark. Recently the town of Montclair applied to the North Jersey Water Supply Commission for 3 m.g.d. from the Wanaque. Since then the serious shortage of water in the districts to the north and east of the Newark-Montclair-Paterson area seems to have stimulated other municipalities to apply for rights in the Wanaque. Applications actually filed up to Nov. 1, together with three about to be filed, follow: Newark, 25 m.g.d.; Paterson, 25; Passaic, 16; Kearney, 15; Bloomfield, 4; Montclair, 3; Glen Ridge, 1; total applications actually filed 89, to which may be added the proposed applications from Clifton of 6 and from Harrison of 9 m.g.d.

Bayonne notified the commission that it would like a month longer in which it might apply for 20 m.g.d.

The consensus of opinion at the meeting, both on the part of the

\$108,000 Available to Study Engineering Education

The Carnegie Foundation has authorized the appropriation of \$108,000 to be spent in a study of engineering education under the direction of the Society for the Promotion of Engineering Education. The resolution of the Foundation reads as follows: "Resolved. That the sum of \$108,000 be, and it hereby is, set aside for the purpose of making possible a study of engineering education under the direction of the Society for the Promotion of Engineering Education; that of this sum the following amounts be, and they hereby are, made available to the society: \$24,000 during the present fiscal year, \$12,000 during the fiscal year 1924, with the understanding that if, in the judgment of the executive committee, substantial progress shall have been made in this study by Jan. 1, 1925, the balance of the \$108,000 will be made available to the Society as follows: \$24,000 additional during the fiscal year 1924, \$48,000 during the fiscal year 1925."

Philadelphia Sewage-Works Put in Operation

Special Correspondence

The first unit of Philadelphia's extensive new sewage-works was put in operation on Oct. 29. The plant is known as the North East Sewage-Works, and is located on the Delaware River, between Erie Ave. and Lewis St. It consists of 32 110-hp tanks and 80 sludge drying beds, and has a capacity of 60 m.g.d. The plant is designed to provide for 300,000 people, and is one of four similar units to be constructed at the North East works, which will have a total daily capacity of 250,000,000 gallons. The cost of the new plant was \$1,330,000.

Besides the North East plant, the city will build two others, known as the South East and the South West sewage-works. The capacity of the three plants will be 800 m.g.d. The South West plant is under contract.

municipalities represented and those of the North Jersey District Water Supply Commission, was that the commission should immediately make estimates on the cost of a joint Wanaque-Ramapo development along the general line recommended to Bayonne by Mr. Weston. Strong sentiment was also expressed in favor of giving careful consideration to the acquisition by the commission for the various municipalities in North Jersey of the properties of the East Jersey Water Co. and its associates, and also of the Hackensack Water Co. which supplies altogether some 50 municipalities.

The representative of Hoboken stated that his city had just made a contract with Jersey City for five years under which the latter would supply Hoboken, the price to be \$77.50 p.m.g. against \$138 p.m.g. for water from the Hackensack Water Co. which has supplied Hoboken for a number of years past. Bayonne is now supplied from the Little Falls filter plant of the East Jersey Water Co.

San Francisco Engineers Discuss Needed Contract Changes

Lower bids on construction work could be secured if owner and engineer would prepare contracts and specifications with more regard to the contractor's point of view; this was the keynote of discussion at a meeting of the San Francisco Section of the American Society of Civil Engineers on Oct. 16. The paper of the evening was "The Contractor and the Engineer," read by H. Nunn, general manager of the Contractor's Association of northern California and former state highway engineer of Oregon. Both engineers and contractors entered into the discussion but the contractor's point of view was presented and defended by both sides, indicating that changes in contract forms which would relieve the contractor of undesirable limitations would be generally welcomed.

Mr. Nunn's classification of all highway contractors in Oregon showed that half of them had engineers in charge of their work or were formerly engineers themselves. If the reverse of that could be true, it was pointed out, a better relationship between engineer and contractor would obtain. Points emphasized during the evening were as follows:

The contract forms themselves are most urgently in need of improvement and the administration of contract terms follows as a close second. The contractor must bid high enough to cover the cost of work plus a profit, a profit commensurate with the risk the specifications impose.

When a contractor makes a competitive bid he must base his figures on the minimum cost the specifications will permit. Specifications should therefore be definite as to what will be accepted.

Considerable discrepancies between the engineer's estimate and the contractor's bid may be due to hazards imposed by contract forms. The engineer makes his estimate without any uncertainty about administration of contract terms, while the contractor's bid must take into account all hazards expressed or implied by the contract.

East Jersey and Associated Water Companies Consolidate

A merger of the East Jersey, Passaic, Aquackanonk, Montclair and Kearney Water Companies under the name of the Passaic Consolidated Water Co. has been effected. The merger was approved on Oct. 30 by the Public Utility Commissioners of New Jersey. It is reported that the new companies will apply to the commission for authorization of \$8,000,000 of 6 per cent mortgage bonds and \$3,500,000 of capital stock, as against book assets on Dec. 31, 1922, exceeding \$13,000,000.

The five companies jointly own water diversion rights, pumping and filtration plants at Little Falls, a large trunk main and a storage reservoir, together with the water distribution systems that supply Paterson, Passaic, Clifton and Montclair, and have contracts for supplying water in bulk to other communities. In March of this year the entire property was valued at \$11,500,000 for rate-fixing purposes.

Iowa Water-Works Men Discuss Dozen Topics

Well Supplies for Small Water-works,
Records, Inspection, and Publicity
Draw Lively Interest

Engineering News-Record Staff Report

Water-works operators and others interested in water supply from eight Middle West states attended the ninth annual meeting of the Iowa Section of the American Water Works Association, Oct. 24, 25 and 26, at Ames, Iowa. While the papers ran the whole gamut from finance to laboratory control of quality, together with "fringe" subjects of electrolysis and city grading for insurance rates, the liveliest discussion revolved around well supplies and tastes and odors. The latter subject was on the program only as a "round table" discussion but it was good for a full hour and a half, winding up in a detailed account of troubles with filters in the fall due to surface sand clogging and methods to lengthen runs.

A paper on "Operation Records for Small Water-Works" by Earle L. Waterman, associate professor of sanitary engineering, State University of Iowa, led to the appointment of a committee to co-operate with similar committees of the national association or of other sections. Prof. Waterman estimated that of 500 plants in Iowa 490 deliver less than 3 m.g.d. and 464 less than 0.5 m.g.d. In this last group the memory of the plant superintendent is too often the principal repository of records and what the old operator knows is not inherited by a newly appointed one. Reports are required at frequent intervals by the State Board of Health and the State Public Utilities Commission. If daily records are kept these periodical reports are not a burden.

PUBLICITY METHODS

J. J. Hinman, Jr., associate professor of sanitation and chief of the water laboratory division, State Board of Health, University of Iowa, in his paper on "Publicity at the Water Plant" described educational and publicity methods used in taking the public into the confidence of the water-works officials. If the people knew the truth about their own supply they would object less to what they call "chemical doping" for their own protection. An exhibit of the small amount of alum necessary to coagulate 1,000 gal. of or liquid chlorine in a tube to disinfect the same amount of water will usually disarm the most confirmed complainant.

The Ames college and town shallow well supplies described by P. F. Hopkins, city engineer, and C. S. Nichols, professor of sanitary engineering, Iowa State College, came in for much discussion, particularly condemnatory discussion of the college supply, which consists of wells in experimental hog lots on low ground between the town and college, with a sewer (having poor joints) on one of the sloping banks. While the original 100-ft. wells always showed an absence of pollution, an additional well, driven during the war was found full of gas-forming aerogenes and some B.coli by the college water analyst when he returned from service. No analyses were made during the war. No attention was paid to his warnings nor to his insistence that the well casing must be leaking. In fact, the validity of his tests were attacked

A. G. C. and Road Builders To Meet Jointly

A joint meeting of the Associated General Contractors and the American Road Builders' Association will be held in Chicago on Thursday, Jan. 17, 1924, to discuss various matters of importance to the membership of both organizations. This joint meeting has been made possible by the proximity in dates of the annual meetings of these organizations in Chicago. The 1924 convention of the American Road Builders' Association will be held Jan. 15 to Jan. 18 inclusive, while the Associated General Contractors meet the following Monday, Tuesday and Wednesday. All the officers, the executive committee and the heads of the twenty-eight chapters of the Associated General Contractors will, however, be in Chicago the previous week. Many of the members of the organization also will be in Chicago that week attending the convention and road show of the American Road Builders' Association. Plans accordingly have been made for the joint meeting. Details of the program will be announced shortly.

although all of the old wells continued to show the usual excellent results. Finally the casing had to be drawn because it became clogged with sand. Nearly every joint was found defective. Daily analyses are now routine and the sanitary engineering department hopes some time that the aesthetic's objections to hogs around the well houses may be removed though it is conceded that it will probably be easier to "pull up the wells and sell them for post holes" than, under the political control of grounds supervision existing, to re-allocate the hog pens and pastures.

Dr. Max Levine, associate professor of bacteriology, Iowa State College, and Clair S. Linton, research assistant, have been working for several years on 123 bacterial strains of soil and intestinal origin to differentiate B.coli from B. aerogenes. Satisfactory methods based largely on reduction of various carbohydrates have been developed, rather than the former methods of the inhibition of attenuated strains by bile and phenolated broth.

The well discussions followed papers by Dr. Edward Bartow, head of the department of chemistry, State University of Iowa, H. V. Pedersen, state sanitary engineer, and Dr. S. W. Beyer, dean of industrial science and head of geology, Iowa State College. Dr. Bartow described an unusual seasonal variation of iron in the well water supply of Benham, Ky., from 1.5 p.p.m. in December to 65 p.p.m. in February. Mr. Pedersen emphasized location and proper precautions against surface and pump-pit contamination. Dr. Beyer sounded a warning against the dangers of ground-water depletion by extravagant waste.

George W. Fuller, president of the national body, spoke on his recent inspections of European water and sewage plants. Double filtration seems to be on the increase both in England and on the Continent.

The newly elected officers of the section are as follows: Chairman, H. F. Blomquist; vice-chairman, Dr. Max Levine; directors, L. O. Minor and Thomas Healey. By constitutional requirement the next meeting will be held at Iowa City.

Making Railroad Service Attractive to the Engineer

*Extract from Letter to a
Recent Technical Graduate*

Sir—In reply to your application I wish to advise that at present there is a vacancy for a rail inspector on the Blank Division of the Blank R.R., which pays a salary of approximately \$83 per month.

The duties are to make daily inspections of the track structure for defects and failures, together with frequent assignments to field and office work of the engineering corps. This position should be of interest to a young technical graduate who is desirous of starting in a railroad engineering career as the general experience gives a practical first-hand knowledge of track and other structures and should be of lasting benefit as he progresses, through promotion, to the various grades in the engineering department, which are rated as follows:

Chairman	\$110 per month
Rodman	120 " "
Inspector & Drafts-	
man	140 " "
Transitman	165 " "
(Signed)	
Division Engineer.

Calendar

Annual Meetings

AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS, St. Petersburg, Fla.; Annual Convention, Atlanta, Ga., Nov. 12-16.

CITY MANAGERS ASSOCIATION, Lawrence, Kansas; Annual Meeting, Washington, D. C., Nov. 13-15.

FEDERATED AMERICAN ENGINEERING SOCIETIES, Washington, D. C.; Annual Meeting, Washington, D. C., Jan. 10-11, 1924.

AMERICAN ROADBUILDERS' ASSOCIATION, New York City; Annual Convention, Chicago, Jan. 14-18, 1924.

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York City; Annual Meeting, New York, Jan. 16-18, 1924.

ASSOCIATED GENERAL CONTRACTORS OF AMERICA, Washington, D. C.; Annual Meeting, Chicago, Ill., Jan. 21-23, 1924.

AMERICAN CONCRETE INSTITUTE, Detroit, Mich. Annual Meeting (20th anniversary), Chicago, Ill., Feb. 25-28, 1924.

Western Society of Engineers at a luncheon on Oct. 26 was addressed by A. A. Sprague, commissioner of public works, Chicago, on the subject of "What the Engineers Can do for the City."

The South Carolina Chapter of the American Association of Engineers held its annual meeting at Columbia, S. C., Oct. 26, with an attendance of 64. Officers for the coming year were elected as follows: President re-elected, L. M. Fisher, associate sanitary engineer of the United States Public Health Service, Columbia, S. C.; vice-presidents, L. S. LeTeller, head of the department of engineering, the Citadel, Charleston, S. C., and Harwood Beebe, municipal engineer, Spartanburg, S. C.; and secretary-treasurer, Perry M. Teeple, associate professor, school of engineering, University of South Carolina.

Personal Notes

EDWARD M. CRAIG, JR., Wanaque, N. J., is now sanitary engineer for the North Jersey District Water Supply Commission, engaged in providing water supply for metropolitan New Jersey, under direction of Weston & Sampson, consulting sanitary engineers, Boston, Mass. Mr. Craig until recently was assistant sanitary engineer with the Alabama State Board of Health.

THOMAS A. MARTIN, Los Angeles, Calif., is connected with the Lynch Cannon Engineering Co., as engineer in charge of erection of Union Pacific railroad shops. He previously was in charge of construction work for Whitehead & Kales Iron Works of Detroit, Mich.

A. P. SMITH, Charlotte, N. C., formerly engineer for the Nashville Bridge Co., Nashville, Tenn., is now engineer for the Southern Engineering

Co., Charlotte, N. C., whose business is structural steel construction.

EDWARD B. DARLINGTON has been appointed project manager of the Minidoka project of the U. S. Reclamation Service in Idaho, with headquarters at Burley, Idaho. He will have local charge of the irrigation works in that vicinity, including the Minidoka dam, power plant, pumping station and canal system. Mr. Darlington for several years has had charge of operation and maintenance of the Twin Falls-Salmon River irrigation project, and later was chief engineer of Twin Falls North Side Land & Water Co., at Jerome, Idaho. During the past year he has investigated several irrigation projects for the State Bond Commission of Idaho.

DAVID ANDERSON, chief engineer of the Armored Concrete Construction Co. of Malmö, Sweden, recently came to this country for a two months' tour of eastern United States, Canada and the Middle West, to be devoted to the study of engineering and construction work in general and reinforced concrete in particular. Besides the firm he represents, he travels also in behalf of the Manufacturing and Industrial Society of the City of Malmö.

RANDALL E. EVANS, Queens, Long Island, N. Y., has changed from structural engineer with McClellan & Junkersfeld to the same position with Stevens & Wood, engineers, New York City.

J. B. JONES, Houston, Texas, is now doing field engineering work in the valuation department of the Southern Pacific R.R. He was formerly a draftsman in the maintenance-of-way department.

C. CLIFFORD CLARK is now associated with the Roxana Petroleum Corp., Arkansas City, Kansas, as drainage and sanitary engineer. He was previously a draftsman with the Marland Refining Co., at Ponca City, Okla.

W. E. BARLOW, formerly assistant superintendent of the H. P. Burgard Co., is now superintendent on concrete construction work for Rock Bros. & Griffin, at Lowville, N. Y.

NORMAN EAGER, Carbondale, Ill., has been made a junior highway engineer. He previously served as draftsman on highway work in Pennsylvania.

HERBERT HOEFER has changed his association from engineer with Temple & Burrows, Davenport, Iowa, to engineer with the Building Products Co., Toledo, Ohio.

GEORGE D. HALL, Auburn, Ala., has become superintendent of construction for the Opelika Lumber and Construction Co., Opelika, Ala., after having done similar work for the West Point Iron Works, West Point, Ga.

WALTER E. GILLHAM announces that BENJAMIN F. COOK and W. EMERY WHITE, who have been associated with him for a number of years, are now members of the firm, which is now known as Gillham, Cook & White, consulting engineers, and which is now located at 409 Interstate Bldg., Kansas City, Mo.

T. J. STRICKLER, formerly chief engineer of the Empire Gas & Fuel Co. of Bartlesville, Okla., is now associated with F. C. Hamilton, consulting engineer, 60 Wall St., New York City.

STUART B. OVER, formerly senior assistant engineer in the Valuation Division of the Interstate Commerce Commission, and FRANCIS TINGLEY, formerly supervisor of overhead lines for the Washington Railway & Electric Co., Washington, D. C., have formed a partnership under the name of Over & Tingley to do general engineering, the address being Upper Darby, Pa.

PHILIP P. SHARPLES, formerly manager of the General Tarvia Department of The Barrett Co., has entered private practice in highway engineering. He has been retained as consulting engineer by the Palos Verde Co. to design and construct roads and pavements in their development at Redondo Beach, Calif.

Obituary

MORTIMER S. SMITH, assistant division engineer of the New York State Highway Commission and for 28 years associated with the state engineer's office in New York, died Oct. 29 at his home in Rochester, N. Y., after a short illness; he was 51 years of age. Mr. Smith was born in Rochester and educated in private schools. He spent four years in Scranton, Pa., as resident engineer for the Delaware, Lackawanna & Western R.R., otherwise his work was all in Rochester.

EDWARD E. SANDS, consulting engineer of Fort Worth, Texas, and for five years city engineer of Houston, Texas, died at the home of his father in Milwaukee, Wis., Oct. 27, aged 46 years. A native of Columbus, Ohio, Mr. Sands was graduated from the University of Wisconsin with a B. S. degree in civil engineering in 1900, receiving his C. E. from the same institution in 1906. During the two years following his graduation he was an instructor in civil engineering at the university, spending his summers as city engineer of Sparta, Wis. In September, 1902, he entered the U. S. Reclamation Service. He became designer and builder of the South Canal of the Uncompahgre Valley project in Colorado, later was in charge of the Uncompahgre project, and was project engineer on the Grand Valley project. Leaving the Reclamation Service for a few months in 1910, he became associated with J. G. White & Co. as construction superintendent in Washington State. Mr. Sands returned to the Reclamation Service in 1911 for a year, then went to Canada as supervising engineer on Canadian Pacific irrigation development. From there he went to Houston, Texas, as city engineer, resigning in 1918 after five years' service to enter private practice. While in Houston he designed and built the city's activated sludge plants, the largest of their kind, and designed most of the terminal facilities for the Houston ship channel. Since Oct. 1, 1922, he had been a member of the consulting firm of Hawley & Sands, designing and supervising water and sewerage plants for many Texas cities, among which was the Fort Worth \$1,250,000 sewage disposal plant. Mr. Sands was a member of the American Society of Civil Engineers and past-president of the Texas section of the society.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Manufacturers Oppose Ban on Trade Statistics

Important Issues Involved in Tile Maker's Case Now Before Dept. of Justice

In the draft of a proposed consent decree in the case of United States vs. Tile Manufacturers' Credit Association et al., it is proposed by the Department of Justice to enjoin the defendants in the mentioned case from collecting certain types of statistical and other information. It would be provided, however, that such association might receive and compile, for transmission to any government agency, such information and statistics as such government agency might request as to production, stocks on hand and prices. However, such association would be restrained from distributing information so collected among its members. The permissive features of the proposed decree follow the general lines of the consent decree entered in the case of the Gypsum Industries Association, which made no mention of the subject of statistics.

Through its counsel, Nathan B. Williams, the National Association of Manufacturers has urged that in the public interest the draft of the decree be modified by the elimination of all reference to government departments. The collection of information by government departments, it is pointed out, is properly controlled by statute. The association has further urged that in the description of permissible activities of trade associations cost-accounting be included and that such decree carry the following paragraph relating to the subject of statistics:

RECORD OF FACTS WANTED

"To periodically or otherwise collect and make currently and otherwise available to those interested the facts relating to capital employed, power used, wages and [or] taxes paid, fuel consumed, machinery employed, and like pertinent trade information, production, sales, shipments, and stocks on hand of tiles and the prices obtained therefor, all of such being a record of accomplished facts."

In further recognition of the public interest to be protected the manufacturers' association has suggested that in addition to the availability of such statistics to those interested a prohibition might properly be contained in such decree against the misuse of otherwise legitimate activities and information in furtherance of any agreement or conspiracy to fix prices, limit production, restrict sales, divide territory, or in any manner restrain lawful competition in commerce.

The manufacturers' association has pointed out the vital necessity of business information and the serious consequences to the business fabric if the proposed decree should be entered in its present form. Such a decree would, Mr. Williams states, serve notice upon all trade associations that the Department of Justice regards the collection

of statistical and other trade information, because occasionally misused, within the condemnation of existing law, and to be prohibited in so far as the Department of Justice was able to accomplish that end.

Slate Producers Investigate Nailing Problem

The National Slate Association, as part of its program to assure the public satisfaction in uses of slate, is conducting an investigation to determine the proper kind of nails to use for applying slate roofs. Architects, engineers, roofers and manufacturers of nails of all kinds are co-operating in this work. Results of this survey will be made known at slate industry meetings in New York in January.

Sixteen Companies Fined \$20,000 for Sherman Law Violations

Fines aggregating more than \$20,000 were imposed Oct. 30 for alleged violation of the Sherman anti-trust law upon sixteen heating and plumbing defendant companies of the Middle West by the Federal Court in Chicago, in the case of the United States vs. James B. Clow & Sons, et al., Attorney General Daugherty was advised by Roger Shale, special assistant to the attorney general, who, under direction of Mr. Daugherty, has been in charge of the case. The sixteen companies entered pleas of guilty.

The government at the same time the court imposed the fines dismissed the first of the two counts of the indictment returned against the defendants. The companies involved and the fines imposed follow:

James B. Clow & Sons.....	\$4,000
Stardard Sanitary Manufacturing Co.....	4,000
Kellough Mackey Co.....	3,000
I. Wolff Manufacturing Co.....	3,000
Well-McLain Co.....	2,000
Western Plumbing Supply Co.....	500
Davies Supply Company.....	500
National Plumbing & Heating Supply Co	500
Whitney & Ford.....	500
Illinois Malleable Iron Co.....	500
Enterprise Plumbing Supply Co.....	500
Walworth Manufacturing Co.....	500
Hoescher Bros.....	200
S. Deschauer Co.....	100
Quinn Supply Co.....	100
Weir & Craig Co.....	100
	\$20,000

The second count of the indictment against the firms charged the defendants with having conspired to fix and maintain uniform and non-competitive prices for plumbing and heating apparatus and fixtures sold to retail dealers and master plumbers in several states in the Middle West. The scheme forming the basis of the second count was said to have been carried out largely through the instrumentality of a publication known as the "Clow Bulletin." This bulletin, the Department of Justice said, embraced several of the objectionable practices engaged in by so-called open-price associations. The bulletin was distributed and used by approximately 4,500 master plumbers, 415 jobbers and 100 steamfitters.

Hydraulic Turbine Business Taken Over by Newport News Company

An arrangement has been effected between the Wellman-Seaver-Morgan Co., Cleveland and Akron, Ohio, and the Newport News Shipbuilding & Dry Dock Co., Newport News, Va., whereby the latter company has taken over the future hydraulic turbine business of the Wellman-Seaver-Morgan Co., including the patterns, drawings, data, patents, patent applications, developed and undeveloped inventions and complete records, the results of their years of experience in the hydraulic turbine business. The sales offices of the Wellman-Seaver-Morgan Co., in New York, San Francisco and Birmingham will continue to function as heretofore and will represent the Newport News company in hydraulic turbine work. The Wellman-Seaver-Morgan Co. will complete its present hydraulic turbine contracts without reference to the Newport News company. Future contracts will be taken by the Newport News company.

This change in policy according to a joint statement of the presidents of the two organizations, Edwin S. Church and Homer L. Ferguson, will enable the Wellman-Seaver-Morgan Co. to handle all its other lines of work to better advantage and will enlarge the work of the Newport News Shipbuilding & Dry Dock Co.

Cut Made in Varieties of Hollow Building Tile

Manufacturers of hollow building tile together with representatives of distributors and consumers of this commodity met Oct. 19 in the Division of Simplified Practice of the Department of Commerce, Washington, D. C., and unanimously adopted as the future standard line 11 sizes of load-bearing wall tile, 6 sizes of partition tile, 1 size of furring tile, and 1 size of book tile. This action reduces former sizes from between 40 and 50 to 19.

A standard weight for each standard size was also adopted. This in itself is a further simplification, as heretofore there has been a great variety in weights of tile of the same size. Agreement was also reached that the permissible tolerance or allowable variation in weight shall not exceed 5 per cent over or under the standard; also that maximum variation in the major dimensions—length, width, and height—shall not exceed 3 per cent plus or minus.

The general adoption of these standards by architects, engineers, and builders will facilitate their work and tend to lower construction costs. The action of the conference marks another step forward in Secretary Hoover's program for eliminating waste in industry through reducing variety in commonly used commodities.

Cast-Iron Pipe Production

Based on returns from twelve establishments in the United States and confined to bell and spigot pressure pipe, statistics on the production, orders, sales, and shipments of cast-iron pipe for the month of August, 1923, have been issued by the U. S. Department of Commerce. Production during the month totaled 84,588 tons, while shipments amounted to 84,843 tons.

Industrial Works Celebrate Fifty Years of Crane Manufacture

In commemoration of its fiftieth anniversary the Industrial Works, Bay City, Mich., manufacturers of locomotive cranes, buckets and pile-drivers, held a celebration, sales conference and banquet last month. Addresses were made by William L. Clements, president, C. R. Wells, secretary and Ernest B. Perry, general manager. The attendance of members of the organization and guests was about 300.

The records of the beginning of the Industrial Works in 1873 show a working force of about 30 men operating in a 75 x 100-ft. factory building. The

200-TON CRANE TESTED AT COMPANY'S 50TH ANNIVERSARY

plant of today covers twenty-nine acres, comprises fifty-nine buildings with 440,000 sq.ft. of covered floor area, served by five miles of railroad track, and in normal times gives employment to about eighteen hundred men.

At the sales conference were present company representatives from all principal points of the United States, Canada, Cuba, and South America. During the conference the representatives witnessed the testing of a 200-ton Industrial crane for the Norfolk & Western R.R., one of the largest cranes in the world.

Business Notes

BARRETT Co. announces the resignation of Philip P. Sharples, technical adviser, after a period of 20 years of service with the organization. Further details will be found in the "Personal Notes" column of this issue.

MORRISON & RISMAN Co., Buffalo, N. Y., dealers in railway track equipment, announce the establishment of a district sales office in the Ulmer Building, Cleveland, in charge of R. B. Morrison. Warehouses are being equipped at Cleveland, in addition to those already in service in Philadelphia, Buffalo and Lebanon, Pa.

Too Little Time Allowed for Preparing Bids

Equipment Manufacturers Receive Scant Opportunity for Study of Problems on Proposed Work

BY CHARLES G. RICHARDSON
Builder's Iron Foundry, Providence, R. I.

In the following discussion Mr. Richardson calls attention to a practice which is objectionable from many angles. How can the maker and user of equipment cooperate to prevent it? Comment is invited from other manufacturers and from engineers or state and city officials suggesting remedies.—EDITOR.

WE manufacturers of municipal equipment have a grievance: it is the shortness of the time interval usually allowed between the contract advertisement and the date of receiving bids. Engineers often and properly take many months in the preparation of their plans and specifications and the majority of these are admirable examples of draftsmanship and clearness. But once this work is done the time for the preparation of the contractor's proposal apparently receives scant consideration.

I am referring particularly to contracts for waterworks, sewage disposal and filtration. Perhaps two weeks is the average interval between the advertisement and the final date for bidding. Within this time the manufacturer must send a deposit for the plans and specifications, requiring frequently nearly a week for their receipt, and there is left only two or three days to study the various problems involved, perhaps design special equipment, prepare drawings and specifications, and get them all, together with formal prices and deliveries, into the hands of the inquiring bidders in time for the latter to make use of them.

Meanwhile the bidders themselves are in an even worse turmoil in figuring the complete contract and the total result is all too often a proposal far less complete and acceptable to every one concerned than would have been possible under a longer time allowance. Four weeks is none too long to give manufacturers and bidders on such contracts a chance to prepare a carefully considered offering, one not only satisfying to the conscientious manufacturer of equipment but also most suitable for the job.

Isn't there some way, by a little more forethought, of avoiding this rush, typically American, in work which is highly deserving of careful and detailed attention?

Weekly Tips for Manufacturers in Construction News

Heretofore reports on machinery and building materials have been published in the Unclassified columns of Construction News. Beginning next week such reports will be found in Construction News under the heading Materials and Equipment. This week's items are as follows, all verified:

PROPOSED WORK

Rock Asphalt—New Orleans, La.—W. Ball, purch. agt., City Hall, soon takes bids 300 tons Uvalde rock asphalt. A. Black, compr. Dept. Pub. Property.

Rock Crushing—Manitowish, Wis.—Plans to purchase rock crushing outfit during 1924. \$6,000. A. H. Zander, city clk.

Steam Roller or Street Sweeper—Fairbault, Minn.—Plans to purchase steam roller or street sweeper. E. Johnson, city clk.

BIDS DESIRED

Cement, Etc.—New York, N. Y.—Nov. 13, by J. Miller, pres. Manhattan Boro, Municipal Bldg., 5,000 bags Portland cement and 2,000 cu.yd. asphaltic wearing surface sand.

Dragline Bucket—Covin, Ala.—D. W. Robins in market for one dragline bucket.

Gravel—Baton Rouge, La.—Nov. 13, by State Hy. Dept., Raymond Bldg., furnishing 30,849 cu.yd. 60% sand clay gravel or as alternate 10,285 cu.yd. washed gravel and 20,563 cu.yd. 40% sand clay gravel for surfacing Federal Aid Project 81, Sects. A and B, St. Francisville-Mississippi Highway, West Feliciana Parish. J. M. Fourmy, ch. engr.

Paving Brick—Youngstown, O.—Nov. 15, by Director Pub. Wks., 250,000 paving brick. \$8,000.

Crushing Plant—Owatonna, Minn.—Nov. 13, by Steele Co., 1 portable combined gravel screen and crushing plant, 8 x 36 in. crusher. R. W. Hosfeld, Owatonna, engr.

Scraper—Plano, Tex.—J. L. Aldridge taking bids Fresno scraper.

Sluice Gates—Exchequer, Calif.—Nov. 20, by Directors Merced Irrigation Dist., Merced, 2 sluice gates, 277 static head operated under 100 ft. 28-30 ft. to discharge, 6 ft. diam. sluiceway, for Exchequer Dam, here. Starr-Thebo-Anderson, Sharon Bldg., San Francisco, engr.

Railroad Ties—North Bay, Ont.—Temiskaming & Northern Ontario R.R., North Bay, in market for 350,000 railroad ties, \$300,000. S. E. Clement, ch. engr.

BIDS RECEIVED

Road Surfacing Material—New York, N. Y.—See "Streets and Roads."

CONTRACTS AWARDED

Street Sweeper—Hanford, Calif.—Motor driven street sweeper to S. S. Smith, 62 Market St., San Francisco, \$7,200. Noted Oct. 20.

Equipment and Materials

Paving Mixer for City Work Designed for Low Headroom

For city paving work where a large capacity paver is desired, the Koehring Co., Milwaukee, has developed a special design of headframe on its 21E paver.

The uprights supporting the sheaves through which the charging skip cables run are bolted and hinged in such a way that after the bolts are removed the upper framework may be tipped back by the skip hoist clutch, thus reducing the height of the machine, and allowing it to pass beneath low telegraph wires and other obstructions.

The minimum height from ground of the paver with this special frame is 10 ft. 9 in. with truck wheels, 10 ft. 11 in. with half-length multiplane, and 11 ft. 2 in. with full-length multiplane. This arrangement also permits the loading of machine on a flat car for shipment without any dismantling further than the boom and skip.

General Purpose Pumping Unit

A contractor's general purpose pumping unit, consisting of a standard 2½ in. American centrifugal pump direct-connected to a New Way gasoline engine, the whole outfit being mounted on a cast-iron base, has recently been placed upon the market by the American Well Works, Aurora, Ill. Among

the advantages claimed for it by the manufacturer is the connection of the pump to the engine through a flexible coupling, the shaft being supported on a pedestal bearing. This feature is designed to insure long life for the equipment. In addition, a thrust bearing is provided to meet the most rigorous conditions of general service.

The cast-iron casing of the volute type may be swung on its bolts so that the discharge opening may have any of eight positions. The suction nozzle is cast in the casing and companion flanges are furnished for suction and discharge openings. The impeller is of cast iron, machined and balanced.

The unit is made in only one size and is designed for heads up to 75 ft., with a delivery, under field conditions, of from 50 to 250 gal. per minute. Under a 50-ft. head the pump, operating at 1,000 r.p.m., delivers 120 gal. per minute. The manufacturer emphasizes the compactness of the unit which occupies a floor space of 3 x 1½ ft.

Publications from the Construction Industry

Truck Loaders—GEORGE HAISS MANUFACTURING CO., INC., New York, presents information on its path-digging truck loaders in a 28-p. illustrated pamphlet just published. The equipment consists of an endless chain of buckets mounted on a crawler-driven chassis with special material-gathering and discharge features. Operating data are presented to indicate the working capacity of the machine and the design of the loader is explained in detail.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

The Industrial Situation as Shown by Industrial Expansion

Whether business is good, bad or indifferent can best be judged by the rate at which industrial building is going on. When plants and factories are multiplying and expanding it is reasonable to suppose that the owners look with confidence to the future. Heavy industrial building not only gives employment to construction men, but also means many orders for machinery and equipment. If, on the other hand, industrial expansion is below normal the reverse is of course true.

Contracts awarded on industrial projects in the first nine months of 1923 amounted to \$187,648,000, against \$133,178,000 in the same period of 1922, according to *Engineering News-Record* which published awards of \$40,000 and over. This is an increase of \$54,470,000 and will probably place this year's total above that of last year. But it is note-

worthy that most of this increase occurred in April, when \$43,000,000 worth of work was placed under contract. May, June and July awards were heavier than those of 1922 and followed the same trend, as shown by Chart 1. Since August, however, the contracts have been notably lighter than in the same period last year.

This falling off in industrial construction is quite general throughout the United States and Canada, the exceptions being the South and the region west of the Mississippi. The following table shows the situation in each section:

	No.	Value	No.	Value
N. E.	158	\$20,765,000	175	\$520,680,000
Mid. Atl.	282	\$7,991,000	236	\$6,813,000
South	53	\$8,325,000	82	\$6,605,000
Mid. W.	334	\$4,792,000	437	\$62,128,000
W. of Miss.	79	\$7,703,000	170	\$40,982,000
Far W.	60	\$7,602,000	126	\$16,440,000

U. S. Total. 957 \$133,178,000 1,126 \$187,648,000

(Concluded on p. 785)

Production and Materials Stocks in Eleven Cities

Plenty of Brick, Cement, Lumber and Other Materials—Slight Drop in Steel Output

Steel—Production of steel ingots during October averaged between 3,000,000 and 3,200,000 tons, against 3,159,283 for the month preceding. This slight drop is seasonal and indicates satisfactory production conditions. Mills are operating at about 80 per cent of capacity. Demand, though low, is much better than was expected several months ago. No indications, however, point to a heavy production schedule for the coming winter.

Lumber—The total output is now about 2½ per cent above normal, against 6 per cent above, one month ago and 2 per cent below normal one year ago. Production, shipments and orders, however, for the four weeks ending Oct. 20, show substantial gains over the preceding four weeks and also over the corresponding period in 1922. While shipments of Western fir to the Eastern states have declined somewhat owing to Japanese demand, Southern pine, which furnished 36 per cent of all lumber cut in the United States in 1922, has been able to meet the demand and to prevent any danger of lumber shortage. The lumber movement, according to the National Lumber Manufacturers' Association, is shown in the following table:

	Four Weeks Ending	
	Oct. 20, Ft. b.m.	Sept. 22, Ft. b.m.
Cut.....	1,113,268,502	1,076,178,223
Shipments.....	1,006,228,403	939,801,763
Orders.....	1,022,862,571	977,305,153

Cement—Production during the first nine months of this year totaled 101,016,000 bbl., against 81,563,000 for the corresponding period in 1922, according to the Geological Survey. With a gain of 23 per cent in production and only 18 per cent in shipments, a total of 5,492,000 bbl. were available, as a reserve stock for the nation, on Oct. 1, as against 4,724,000 on hand one year ago.

Brick—The report of the Common Brick Manufacturers' Association of

America as of Oct. 1, shows 307,633,000 burned brick on hand at yards throughout the country, compared with 250,176,000 for the preceding month. Orders on books have increased during the last thirty days and production is preceding at an unprecedented rate in the face of the fact that 18,953,000 brick have been imported from Canada, Holland and Germany during the three months ending Sept. 30.

San Francisco—Stocks of building materials are large and easily obtainable, with the exception of blue annealed and black steel sheets and rivets.

Los Angeles—Demand steady and supply sufficient in all materials.

Denver—October lumber reserves largest of any month this year. Brick stocks 80 per cent heavier, compared with month ago.

Minneapolis—Ample stocks of all building materials, with some lightening of demand for brick and tile.

Detroit—Lumber dealers' stocks somewhat decreased. Several days required on large deliveries of hollow tile. Only a moderate supply of brick in local yards. Scarcity of Bermudez asphalt.

Chicago—Sewer pipe supply low; deliveries on some sizes take from three to four weeks.

Cincinnati—Plenty of all materials. Cement deliveries fair, compared with scarcity of a month ago.

New Orleans—All building materials in light demand. Stocks of all character are sufficiently abundant, with the possible exception of 4-in. sewer pipe.

Atlanta—Slightly more cement, steel, asphalt and lime on hand, than a month ago.

New York—Brick stocks 50 per cent heavier than winter reserves in any recent year. By the time Hudson River navigation opens up next season, plants along the river will have 600,000,000 brick ready for the spring market.

The Industrial Situation as Shown by Industrial Expansion

(Continued from p. 781)

Average value in 1923 was \$153,000, compared with \$139,000 in 1922.

The actual trends and current conditions in the various sections are given by the charts. Last year October was the banner month, following a slow, fairly steady improvement. This year's peak also occurred in October (\$48,985,000) but there was a high point of \$43,031,000 in April. Since June the curve declined until October, when the \$20,000,000 Kearny, N. J., power project of the Public Service Corporation, swelled the total.

In the last four years the total and the average monthly value of industrial contracts in the United States in this nine-months period were as follows:

1920	\$408,779,000	\$5,419,000
1921	83,160,000	9,240,000
1922	133,178,000	14,797,000
1923	187,648,000	20,849,000

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for in Construction News, pp. 253 to 263, are the following:

Station and Office, Louisville, Ky., Louisville R.R. Co., \$1,250,000.

Tunnel, Oregon, Southern Pacific R.R. Co.

Bank and Office, Dayton, O., \$1,500,000.

Bridge, St. Paul, Minn., Ramsey Co., \$1,500,000.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 253 to 263, are the following:

Hotel, New York; N. Y., M. Gerschless, \$1,250,000.

Hotel, Hot Springs, Ark., to Ault & Burden, Little Rock, \$2,100,000.

Bank and Office, Richmond, Va., to J. T. Wilson, \$1,000,000.

Apartment, Hollywood, Calif., to Hennessey Bros., Los Angeles, \$1,000,000.

CONDITIONS OF MATERIALS STOCKS IN IMPORTANT CENTERS

Stocks on hand in approximate figures, example: (Common brick, Denver, 9,000,000); time required for delivery of carload lots to city job, example: (Sewer-pipe, Atlanta, 4 to 5 days); and stocks on hand in general terms, example: (Hollow tile, Cincinnati, plenty.)

	San Francisco	Los Angeles	Denver	Minneapolis	Detroit	Chicago	Cincinnati	New Orleans	Atlanta	Philadelphia	New York
Sewer Pipe	Large and easily obtainable	No shortage	Supply low	Ample	Plenty in sizes up to 36 in.	Supply low; del. on some sizes take 3 to 4 weeks	Stocks large	Scarcity of 4-in. gauge	Del. take 4 to 5 days	Enough to supply demand	Mill short—age on 15 to 30-in., double strength
Cement	Fairly well supplied	Sufficient; foreign shipments arriving	Enough	Plenty; del. prompt	Ample for present requirements	Very good supply	Del. fair	Plenty	About 65 cars	Shipped from mills as needed	Plenty; dealers' stocks small but mill del. prompt
Lime	Well stocked	Plenty	Sufficient	Enough	Supply good; Plenty del. good	Plenty	Enough	No shortage	About 75 cars	Sufficient	Market well supplied
Common brick	Large reserves	Demand being met	9,000,000	Demand lighter; plenty	Moderate supply in local yards	Sufficient	Ample	Sufficient	Plenty	No reserve stocks	600,000,000 to be ready for Spring del.
Hollow tile	Good and easily obtainable	Supply equal to demand	Stocks low	Large reserves; demand falling	Several days required on large deliveries	Del. take one week	Plenty	Enough	Del. take 4 to 5 days	No reserve supply	No scarcity
Lumber	Very large reserve	Demand not greater than supply	15,000,000 ft.; largest this year	Supply larger owing to slackening of demand	Dealers' stocks decreased	Del. take 30 to 60 days	Sufficient	Stocks ample; pine in light demand	Plenty pine	Stocks in good shape	Del. take 5 weeks from mill
Asphalt	Unlimited native supply	Native reserves large	Sufficient	Ample	Del. good on Mex.; scarcity of Bermudez	Plenty	Ample	No market	About 70 to 80 cars	Sufficient to meet increased demand	Heavy reserves in N. J.
Structural steel	Plenty structural; low on sheets and rivets	Sufficient	Warehouses well stocked	Enough in ware houses	No short—age of local warehouse stocks	Users' stocks low on bars and plates	Warehouse stocks large because of slower demand	Normal	About 4 cars	Supply ample for small ton-nages	Demand for structural active; warehouse stocks sufficient

Tariff Commission Drops Investigation Covering Duty on Logs

The Tariff Commission, by a vote of four to two, has decided that it lacks jurisdiction to investigate costs of production of fir, cedar, spruce or western hemlock logs, mentioned in paragraph 401 of the tariff act of 1922.

Paragraph 401 imposes a duty of \$1 per M. ft. b. m., on these logs, with the proviso that such logs shall be duty free if imported from any country which within a year has not imposed

any embargo or restriction upon its own lumber exports. This conditional duty was aimed at export restrictions imposed by Canada.

The majority opinion held that the flexible provisions of the tariff act did not apply because upon certain conditions the logs could be entered free of duty.

Less Reconstruction in France. Four out of five largest American concerns operating in France, have withdrawn from the field because of belief that

present French financial situation is unfavorable to building. Work is not extensive enough to further attract American builders and French claim ability to operate at lower costs.

Finland proposes to spend \$16,500,000 on public works, railroads, harbors and hydro-electric resources. Recently \$10,000,000 of Finland bonds were placed on the American market.

Conditions in Japan show that the reconstruction program will cover a period from 5 to 7 years. This will radiate prosperity to all part of the Empire.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted.

Valuable suggestions on costs of work can be had by noting actual biddings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Nov. 1; the next, on Dec. 6.

Steel Products:	New York	Atlanta	Dallas	Chicago	Minneapolis	Denver	San Francisco	Seattle	Montreal
Structural shapes, 100 lb.....	\$3.64	\$4.00	\$4.20	\$3.40	\$3.55	\$4.20	\$3.60	\$4.10	\$4.00

Explanation of Prices—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or - signs. For steel pipe, the prevailing discount from list price is given: 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b.

Labor—Concrete laborers' rate, 95c.; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. Tile price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu.yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5 1/2 x 8 x 1 1/2. Prices are all f.o.b. warehouses except C. I. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir, common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on pine lumber. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at \$8.70). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$47.43; 6-in., \$119.

Changes Since Last Week

The current market is characterized by irregularity both as to prices and conditions. The recent recovery in the stock market; an acceleration of retail trade; and the declaration of an extra dividend by the U. S. Steel Corporation are favorable indications.

These are offset, however, by the lack of development in steel demand; lower pig-iron prices, also due to falling demand, a sharp increase in the domestic business mortality; and curtailment in certain manufacturing industries.

Instances of price irregularity are shown in the recent advances in both steel and cast-iron pipe in Atlanta as compared with declines in San Francisco and Chicago. Pine timbers, at the same time, advanced \$2.50 in Dallas and dropped \$1 per M. ft. in New York and Chicago. Linseed oil (an indicator of the paint trade) dropped 3c. in Atlanta, Minneapolis and San Francisco and rose sharply in Seattle. Lump lime, common brick and hollow tile, however, declined consistently in Dallas and Minneapolis as did cement, yellow pine

lumber and common brick in New York.

The iron and steel situation may be described briefly as follows: No. 2 foundry iron quoted as low as \$20@21 per ton at Birmingham. Buyers not quite satisfied that bottom has been reached in iron prices. Coke declining with pig iron. Steel bars still \$2.40, with structurals at \$2.50 per 100 lb., Pittsburgh. Steel consumers show tendency to believe that prices have stabilized at present levels. A very small amount of cutting under is reported, mostly on steel sheets.

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING
AND CONTRACTINGE. J. MEHREN, *Editor*
FRANK C. WIGHT, *Managing Editor*

Volume 91

NEW YORK, NOVEMBER 15, 1923

Number 20

Tax Economics

THE best test of a tax is the return it brings. Secretary Mellon has shown that the excessive supertaxes defeat their own purpose in that the large incomes are annually paying less to the upkeep of government. That these supertaxes are also encouraging tax-exempt bonds with accompanying municipal, county and district extravagance is secondary though important. The Secretary of the Treasury puts the question squarely up to Congress. Shall we continue our present system of taxation and pile up a Treasury surplus at the expense of a proper industrial expansion and out of the pockets of the middle class salaried man, or shall we continue to bow down to the class antagonism which demands a theoretical high tax out of large incomes whether that tax brings in any return or not? Economics and sound finance are on the side of the Secretary of the Treasury. Whether politics is remains to be seen.

Temporary Football Stands

COLLEGE football gatherings last week produced in one day two failures of temporary seating stands, which sent several score spectators to the hospital with serious injuries. Failures of this kind have become increasingly frequent as the assembling of large crowds at sport events has increased, and on the present record temporary stands must be set down as a distinct danger to public safety. Unlike permanent stands, they usually do not receive engineering attention in design and construction. They are decided upon in haste and are entrusted to the rule-of-thumb methods of a carpenter boss; and, representing a speculative expenditure for one-day service, they are apt to be bargained for at lowest price. While such conditions might seem to be most hazardous in the case of a private promoter's enterprise, the irony of fate makes the amateur football stand much the greater hazard. Engineering and architectural skill is ready to hand, in a college town, but it does not seem to be made use of when temporary stands are wanted. From the outsider's viewpoint it is the obvious duty of college authorities to make sure of the safety of their temporary stands before throwing them open to the visiting football crowds. But we fear that under present circumstances, if a stand collapse were to be investigated searchingly to determine how the authorities had carried out this duty, they would not make a wholly creditable showing.

Reinforced-Concrete Roads

THE case for reinforcement of concrete roads is well argued in this issue. There will not be entire agreement of engineers that wire mesh is the superior form of reinforcement, but this may be passed in the satisfaction that engineers, who have long urged that steel had a useful place in pavement slabs, will gain in having their practice so vigorously supported by Mr. Breed's discussion. Great strides have been made in

three years in concrete road slab design. The separation of the slab into two spans by a longitudinal joint, the doweling of all joints, the thickening of the edges of slabs, and, above all, reinforcement itself are all common practices today. And none of these new practices has been more widely taken up than reinforcement. Each year has seen those states which began with a light mesh of steel to check cracking increasing the weight of metal used in the body of the slab and strengthening points of local stress with supplementary bars and frames. There is less need now than a few years ago to bring proof that reinforcement has its use in pavement for rural roads but there is still a world of knowledge required concerning the principles and technique of pavement reinforcing. These subjects both need more consideration than they are receiving in the everyday practice of road design.

Engineering Plus Adventure

RARELY has a group of engineers had a more spectacular or exciting three months than had Colonel Birdseye and his associates this summer at the bottom of the canyons of the Colorado. The running story of the trip in this week's issue is as absorbing as any tale of adventure. It satisfies, as few engineering reports do, the fictional notion of the engineer's life. But more than that it is the initial story of an exceptional engineering investigation carried out under the most adverse circumstances with what appears to be satisfactory success. The Colorado River is to be the scene of some of the most important engineering work of the next generation but that work cannot even be projected properly until more is known of the nature of that practically untraversed canyon, a part of which has become famous for its scenic beauty. This knowledge the Birdseye party set out to supply insofar as a reconnaissance could supply it. This voyage down the Colorado was in reality a preliminary survey with a line of levels carried through with remarkable accuracy, and included a study of dam sites and a record of stream flow, in addition to a fair amount of topographic mapping. When it is remembered that the trip itself, devoid of any of the surveying accessories, has been made only two or three times and, with the exception of the pioneer Powell trip only as an adventure, the Birdseye expedition becomes a notable addition to the annals of engineering.

Work for Engineering Schools

INDUSTRY is going to need 400,000 more persons for positions of responsibility by 1930 besides the replacements in the 1,500,000 administrators and technical experts now employed. This is the conclusion of the National Industrial Conference Board from an extension of current statistics and a consideration of the growing complications of industry. These figures are easy to believe but the collateral assumption that this means a

proportionate burden on the engineering school is not so convincing. It is no doubt a fact that industrialists generally are beginning to have a much better appreciation of the advantages of a technical education in the administration of industry but engineers should not delude themselves into believing that the future executives are all coming from the engineering profession. The report of the Board, abstracted in this issue, partakes of the common failing of industrial leaders of considering the problem of engineering education mainly the most efficient production of human material to fit into the major gears of the industrial machine. Insofar as the changing industrial process is to call for more and more engineers to do strictly engineering work the Board's conclusions are sound. Engineering schools must prepare for a growing increase in that demand. As to the necessity for an engineering training for the future administrator it depends on what one calls an engineering training. From the Board's report and the suggestions of similar nature that industry occasionally offers the proposed training is industrial rather than engineering. It may be that the engineering school can furnish such training better than any other but it should be clearly understood that the products of it are not so much engineers as they are industrialists.

Another Study of Education

THIS problem of fitting engineering education to the needs of the future is so important that engineers will welcome the decision of the Carnegie Foundation to spend \$108,000 to supplement the earlier study made by Dr. C. A. Mann some years ago. The new investigation will be made mainly by the colleges themselves under the direction of a man exceptionally well equipped for the job. Mr. Wickenden has had the dual experience of being an engineering teacher and an industrial leader and in both capacities has made a brilliant record as a student of personnel and training. Any study under his lead, therefore, will have both solid foundation and vision, both of which are sorely needed today in engineering education. One word of suggestion only may be made. The proposed study, though initiated by the Society for the Promotion of Engineering Education, has been surrounded with a good deal of the same kind of thinking that marks the report noted in the preceding paragraph. The men back of it apparently have had the promotion of industry foremost in their thoughts. This is admirable but those who are to spend the Carnegie Corporation's money must not forget that after all there is an honorable and necessary profession of engineering which cannot be made merely the handmaiden of production. If it were to become so the progress of the world would be seriously retarded.

Engineers in Public Service

ENGINEERS in Chicago recently got a layman's frank view of themselves and their profession that was both appreciative and inspiring. Col. A. A. Sprague, commissioner of public works, chief of staff of the Thirty-third Division during the war and president of one of Chicago's largest commission houses, in addressing a noonday meeting of the Western Society of Engineers stated that no men were more needed in the activities of a city than the engineers, but the entire absence of engineers from all bodies selected directly by the citizens he deplored as unfortunate both for the city and the profession. Mr. Sprague asked if there

were some inherent restraint in the engineer tradition that kept engineers from elective offices or whether it was merely choice. By this time engineers must realize they must work out their own destiny. If engineers want to get into public life individual engineers must do it and when they do attempt it the profession must stand back of them. The muddle in the Reclamation Bureau is a point in question.

As to inspiration and activation, Mr. Sprague made four points: The engineer can develop *honest* fact-finding; he best can apply those facts to the proper growth and development of a city; he can help obtain public approval and he can and must co-operate with men who are not engineers without intellectual or technical snobbery. On these last two points Mr. Sprague gave some very wholesome advice which the 300 engineers who overcrowded the room took without wincing. "When engineers are able to humanize their ideas so that the public can understand them, accept them and sense their benefits it will be a progressive step of far-reaching importance, but remember," he said, "you have got to be real human beings yourself before your words will be human. You men have got to help bridge all these human difficulties which are based on human misunderstandings that can be improved. The human factor in all labor and in all achievement is a part of your problem. It lifts the profession out of the mechanical and material and into one of those vital professions which are most worth while."

With leadership like this it is easy to see why the engineering department of the City of Chicago, for the first time in years, is happy, contented and has become once more a "good place to work."

Power and the People

LAST week the voters of the State of New York defeated by an overwhelming majority an amendment to the constitution permitting the development of water power on the state lands in the Adirondack forest. The vote was important to New York because it holds back for an unknown period the imperative development of the power resources of the state, but it is more important as an indication of the temper of the people in this critical issue of power. If this temper is general—and there is no reason to believe that New Yorkers are unique in this respect—the vote is most significant and the kind of thinking it represents must be studied and reckoned with by all concerned with power development.

The present constitution permits the use of 3 per cent of the Adirondack state lands "for the construction and maintenance of reservoirs for municipal water supply, for the canals of the state and to regulate the flow of streams." The proposed amendment provided that this same 3 per cent could be used "for the development of water power for the public benefit, and for the construction, maintenance and operation thereon of ponds, structures, conduits and appurtenances necessary for that purpose." Such development might be by the state or by a lessee of the state under state regulation. Transmission lines were specifically included in the appurtenances but manufacturing or business was prohibited on the state lands. There are about two million acres in the state domain, but by any plans now known only about 2,000 of the permitted 60,000 acres could be used for the power purposes outlined in the amendment. In other words, an extremely small part of the wild land of the state was to be utilized, possibly by the state

itself, possibly by private interests whose profits and rates would be controlled by the state, to develop about a million horsepower by the formation of a few artificial lakes in a country already spotted with natural ponds, the erection of some slightly power houses and the construction of some transmission lines along narrow lanes cut through the forest.

The opposition to the amendment came from two sources—first, the group of nature lovers, made up partly of the private owners of Adirondack land, mostly wealthy men with large forest preserves inaccessible to the general public, and partly of the vociferous minority who make a holy cause of any practical utilization of nature's resources and second, the advocates of state owned power, who are also the opponents of any private power development. The arguments of the two groups were in many respects in mutual opposition, but this they calmly disregarded and worked together to such good effect that practically every influential newspaper in the state came out against the amendment and its only public defenders outside the power companies were a few engineers who have been studying the power resources of the state.

In effect, the arguments against the amendment were as follows: (1) It might prejudice the state's future ownership of its water power; (2) it would destroy the beauty of a state park by the erection of disfiguring power houses and appurtenances and (3) it would permit the exploitation of public resources by private interests (for publicity purposes known in all the literature as the "water power barons") with no compensation therefor. Here is, of course, a curious mixture of state ownership and the nature lover. Just how a state owned power plant is to be less disfiguring than one privately owned was not made clear—but at any rate, and this is the significant thing, enough people accepted one or the other view to defeat the amendment by half a million votes.

The campaign against the amendment and the vote make one thing very clear—there is need of a vast amount of education in the matter of power development. In spite of the experiences of the past few years the people generally take as an amiable scientific prophecy that there will be no more coal in a few generations. It apparently has about the same effect as the recurring predictions of the diminution of the sun's heat. There is, besides, a dense ignorance of the real nature of hydro-electric development. It has not penetrated the general intelligence that for widespread electric transmission economic design requires that steam generation must accompany water generation and that during this period of growing scarcity of coal it is only by the tying in of the available water power to properly located steam stations that electric energy can be delivered at the lowest cost. Further than that, many scattered hydro plants must be tied together to take care of the variations in flow and demand. It follows therefore that for the greatest economy the state, if it develops its own water power most economically for the public good, must either co-operate with the private companies in the distribution of energy or operate its own coal burning plants.

It is possible, of course, that in time our social development may lead to one of these two contingencies but we very much doubt if that time is near or that many of those who voted against the amendment desire either one. Most of them were obsessed with one of two notions, that power development in the Adirondacks

means a ruthless destruction of natural beauty or that even with state control there is inordinate profit in the private development of water power. Neither of these two notions has any basis in fact, but merely to state that has little influence with the public. They need to be educated in the elementary principles of power development, so that they can judge more wisely when such issues as this one arises. If in the long run the people of the United States want publicly owned power they are going to have it. That is what democracy is. But it behooves those who believe that for the next fifty years at least the general good is to be better served by private development to do all they can to put the facts before the people so that they will not be governed by such silly and contradictory arguments as prevailed in New York last week.

A Record and a Promise

LAST spring when everything else seemed to point to a season of unusual prosperity it looked as though the railroads, through their inability to handle the increased traffic, would put a costly check on an otherwise successful year. They were still years behind on their normal betterment program, behind on their maintenance work, without capital for new work, and lacking the ability to raise much new capital because of their low earning power. But the American Railway Association, realizing, probably, that the success or failure of the performance of the railroads in the ensuing months would largely determine the attitude of the new Congress towards them, and realizing as well that if the situation was to be handled successfully it must be done through increased efficiency, set out to increase the number of cars available for the transportation needs of the country by increasing the miles per day per car and the load per car, and also decreasing the number of bad-order cars and engines waiting repairs. In addition to this the railroad companies took advantage of equipment trusts as a means of purchasing rolling stock.

The record of how well this program of increased efficiency was carried out is now a matter of history; approximately 115,000 new freight cars and three thousand engines, a smaller percentage of engines and cars in need of repairs than ever before, the average mileage per car per day increased from 22.5 for the first nine months of 1922 to 27.6 for the same period in 1923, and an increase of 31 per cent in the ton-miles per day.

This is a record of which the railroad companies may well be proud but the best part of it is that it has spurred them on to outline a more comprehensive plan for next year. This plan includes a field of co-operation and use of joint facilities never tried before. Its success will largely depend on the continued confidence of the railroad operating officials in the security of their properties and their ultimate return to a paying basis. As long as they feel that in the near future they will be able again to invite new capital to invest in the railway field so long will they work toward more efficient operation. But once they feel that that their companies are going to be kept from earning a fair return on the capital invested just so soon can the American people expect the collapse of their great railroad structure. The railroad performance in the past ten months has demonstrated that the Transportation Act is, on the whole, fairly just and workable. The incoming Congress will do well if it devotes its attention to its improvement rather than to its destruction.

Reinforcement in Concrete Roads Worth Its Cost

Experience and Experiment Both Give Proof of Increased Strength and Endurance — Quantity and Distribution of Steel Main Problem — Fabric With Edge Bars Best

BY H. ELTINGE BREED

Consulting Highway Engineer, New York, N. Y.

REALIZATION of the basic value of concrete roads and concrete bases has made highway engineers seek zealously to eliminate their defects. Comparison of the use of concrete in highways with its use in structures directed attention at once to the value of steel as a method of giving additional strength. In concrete structures such as buildings and bridges, the use of steel for reinforcement was accepted good practice, and the theory of relative quantities to secure a given strength had been worked out to precision. Obviously, the use of steel in the concrete would give additional strength to highways. But would the expense be justified? It was argued that it would not; that whereas in buildings steel was a necessity to give them rigidity, it was not necessary on a flat surface that had the bearing power of the whole earth beneath it. But meanwhile cracks were developing in the concrete and concrete-base roads, and it became apparent that the bearing power of the whole earth varied widely on different portions of its surface. Other remedies having been tried without success, small quantities of steel were introduced to try to bind together the slab. The results were so encouraging that the use of steel as a binding agent in concrete roads has become general.

Experiment having indicated that the use of steel was advisable as a binding agent in concrete roads, the problems remained of how much steel it was advisable to use, and of how best to distribute it.

Distribution—Cracks first occur when the cement is setting. When cement hydrates the chemical action involved generates heat, and shrinkage inheres in the process of cooling after setting rather than in drying out as was formerly thought. During shrinkage a binding steel is insurance against the progression of cracks, and the greater its distribution the more effective it will be. For instance, in wire with a 6-in. spacing a crack starting at the center of the mesh can progress only 3 in. before it strikes a steel binder that checks it. Thus reinforcement insures against the spread of any cracking that may be started by the stresses involved in the setting-up and curing processes. With the greater distribution of metal there is greater uniformity of strength in the concrete.

Whereas wire fabric provides uniform reinforcement, the tendency of the slab itself is to weakness at the edges. It is wise therefore to give edges additional strength by the use of a steel marginal bar or a thickening, and to hold the slabs together with an interlock or dowels so as to prevent unevenness at the joints and consequent impact.

Amount—For several years opinions varied about the amount of reinforcement it was advisable and economical to use. Two types came into general use, wire fabric and bars. Wire fabric weight for weight and area for area gives greater bond strength than bars on account of the fact that it has a greater superficial area. That wire fabric has more strength than bars

weight for weight and area for area has been demonstrated by tests of the Pittsburgh Testing Laboratory. In these tests:

Three 3-in. round bars of 0.1093 sq.in. average area showed an average strength of 66,663 lb. per square inch, while five No. 8 wires, with a total area of 1.005 sq.in., showed an average strength of 83,490 lb. per square inch, or 25 per cent greater strength. Similarly, three 1-in. round bars with an average area of 1.982 sq.in. showed an average strength of 60,063 lb. per square inch, while eight No. 7 wires showed a total of 0.1944 sq.in. of area and an average strength of 81,237 lb. per square inch or 35 per cent more strength.

Small units of wire fabric reinforcement, because of more complete distribution of the metal, have greater tensile strength and bond strength than larger units of the same total weight and area spaced more widely.

There are other practical advantages of wire fabric that recommend it as a method of reinforcement, such as ease in handling, insurance of full quota of metal, greater facility on making street cuts through the pavement, closer approach to surface, and direct contribution to strength of pavement.

Placing—Most specifications now require that the wire fabric be supplied in sheets. These sheets are shipped in bundles and deposited by the roadside. The wires that bind them together are snipped, and two men, one at each end, lift each sheet and place it. With material woven into a web, no opportunity is afforded to omit any part of it. The engineer on the job is probably on his rounds before the wire fabric is covered, or if he has been absent and wishes to ascertain that it has been laid, he need only drop a hook through one place in the green concrete.

Since the surface is the area of disintegration, the support should be laid as close to it as is consistent with protection from abrasive wear. The generally approved depth at present is 2 in. below the top. It is extremely important that the fabric be laid in place at this depth, and not be simply dropped anywhere in the slab to find its own abode. The carelessness of the latter method has been found by test and experience materially to decrease the value of the reinforcement in preserving the integrity of the slab.

Proper placing of the reinforcement may be accomplished in two ways. The earlier, still most widely-used method is to screed off the pavement at the required depth, usually 2 in. below the top. This is done to remove any irregularities that would prevent the fabric from lying smooth. Then the fabric is placed on this bed and covered with the specified thickness of concrete. There is no opportunity for the metal to bridge or for voids to form under any part of it. There are, if the contractor wishes, two machines now on the market to strike off below the surface. The laying of the concrete above the fabric is accomplished equally well by either the chute or bucket type of discharge, requiring only a little more rapidity in its distribution, which means ultimately a saving in the

contractor's time. If, however, he wishes to avoid the extra operation of screeding, although it is done by men in the time when they would otherwise idly be waiting their turn in operations, he may use the new method of laying.

This second method involves only one pouring and no additional screeding. The wire fabric is laid on a support of thin iron plates set on edge to the desired position. The concrete is then poured through the wire to the required depth and above it to the surface. Then the iron plate supports are slid along by the movement of the mixer, to which they are attached, to be in position to receive the next section of reinforcement.

Openings—Where street openings must be made through the pavement, the rupture of the wire can be accomplished instantly with a pair of wire cutters. A 5- or 6-in. margin should be left between the edge of the opening and the ends of the wire mesh, so that the wires cut may be bent back into loops to which new fabric may be attached when the disrupted area is repaired. When sections of pavement must be torn up, a simple inlay thus renders intact the strength of the reinforcement.

Cost—It would seem that so far as service goes the concrete road reinforced with wire fabric meets the increasing requirements of modern traffic. How about the cost?

We know that reinforcement data compiled by the Ohio State Highway Department show the annual cost of maintenance of plain concrete as compared with reinforced concrete roads. *Engineering News-Record* for July 12, 1923, says that the total yardage of plain concrete roads built in Ohio prior to Jan. 1, 1923, was 4,767,366 sq.yd. The total maintenance cost for the year 1922 was \$106,936, or an average cost of \$0.0223 a square yard. This would be an average cost of \$209.33 for each mile of plain concrete pavement 16 ft. wide. Of concrete reinforced circumferentially and with wire fabric there was laid up to the same date 2,921,002 sq.yd. with a total maintenance cost of \$14,289 or an average of \$0.0043 a square yard. This would mean \$40.36 for each mile of 16-ft. pavement, a clear saving of \$168.97 for every mile, every year.

Actual experience moreover, indicates that the reinforcement prolongs the life of the pavement at least one-fifth. Taking the general average of the life of a concrete pavement to be 20 years, the reinforced pavement will last 25 years. Multiplying the life of the reinforced pavement by the yearly saving in maintenance, we have a saving of \$4,225 to offset the \$1,120 it originally took to reinforce that particular mile, a clear saving of \$3,105. With that in view it behooves any municipality whose annual maintenance charges are over \$0.14 a square yard to consider the wisdom of making a capital investment that will be refunded in maintenance savings.

The conclusion is then that from the standpoint of the public, of road-builders and of engineers, concrete pavement or base, reinforced with wire fabric with edges strengthened and with joints interlocked or with dowels at the joints, adequately meets the requirements of modern traffic.

Bates Road Tests—The truth of this conclusion is sustained by both experiment and experience. The experiments made on the Bates experimental road in

Illinois have been of world-wide significance. In July, 1922, the writer inspected the road. At that time five series of loadings had been run over many different types and variations of pavement laid contiguously, and the destruction of many sections had resulted. It was evident then that plain concrete bases under 6 in. thick were not adequate; even one section 6 in. in thickness showed the beginning of failure.

Since then traffic has been continued, with increased loadings, until a total load of 16½ tons has been used, 13,500 lb. on each rear wheel, in the final runs. In all, over 1,000,000 tons of traffic have been carried. On July 17, 1923, with two more days of the test still to run, only one section with an 8-in. concrete base as foundation for other types of surfacing than concrete was left intact. Definite conclusions should be drawn only from the results of the full test which are not yet available, but this much is evident: the top surface does not protect the base slab from ordinary stresses; and the contrast between the plain and the reinforced-concrete sections of the same thickness and proportions indicates that reinforcement in the bases would be a decided help.

On July 17, 1923, the Bates road had still in service a 6-in. section reinforced with 45 lb. per 100 sq.ft. of wire fabric reinforcement. After subjection to 1,000,000 tons of traffic with loadings up to 16½ tons, this slab is in good condition. The one break in the corner that developed last year was due to impact caused by the failure of the adjoining slab 5 in. in thickness. The cracks that have developed are fine and in four instances have stopped without progression through the slab. All of the cracks are well held together with no spalling or breaking down. The present condition of this slab indicates strength from the fabric reinforcement adequate to the test, which was extraordinarily destructive, half of the total tonnage running on the edge of the pavement, which had no edge strengthening.

Reinforced Bases—That the results of these tests is confirmed by experience is shown by recognition by many engineers who are specifying that their bases under asphalt, brick, wood and stone block, etc., shall be reinforced. High Holborn Road, London, is being rebuilt with a 9-in. reinforced concrete-base using a wire fabric reinforcement for a wood-block pavement. Fulham, London Metropolitan District, is laying wood-block pavement on a 9-in. and 10-in. concrete base reinforced with wire fabric. Holborn, London Metropolitan District, is laying a first-class paved road with a 2-in. asphalt top on a 9-in. concrete base reinforced with a wire fabric.

In this country concrete bases are being reinforced in Richmond, Va., where 40 lb. of wire fabric is being used in a 5-in. concrete base under brick, durax, and asphalt surfacings. In Hudson County, New Jersey, a reinforced-concrete base is laid under granite block across the soft marshes of the Jersey meadows. Other cities like Augusta and West New York are using the reinforced-concrete base.

Examples—The writer's observation and experience corroborate the results of experiment. In 1920, in a pavement in Bennington, Vt., he used 40 lb. of wire fabric per 100 sq.ft. on the narrow sections of the street on either side of the car track under medium to light traffic. Three years later, after an unusual increase

in traffic, there are very few cracks with no opening up. The maintenance has been \$0.002 per square yard per year.

Other reinforced-concrete roads that he inspected nearly three years ago were the Fort Lee Turnpike in New Jersey and the Kearney County Road; the William Penn Highway in Pennsylvania; the Grand River Road in Wayne County, Michigan; the Albany-Schenectady Road in New York; the Babylon-Bayshore Road on Long Island; and city streets in Paterson and Ridgefield, N. J., and in Beacon, N. Y. *Engineering News-Record* of Dec. 23, 1920, gives details of these pavements and others.

In every one, the three years' additional service has made more apparent the beneficial effects of reinforcement. The reinforced-concrete pavements have held better than near-by plain concrete pavements under similar conditions. This was to be expected. The significant point is found in the cost data. As far as the writer has been able to obtain it in detail, it shows that the lower maintenance of the reinforced pavement offsets within half its life the additional cost of the reinforcement.

Conclusion—Considerations of theory, practice and use lead to a tentative recommendation for what is vaguely known as the "average" case. From the "average," each highway problem will vary in respect to some factors still indeterminate such as bearing power of sub-soil, moisture content, temperature stresses, etc. Where sufficient basic facts have not yet been ascertained, we still have to design on empirical generalizations based on observation of the trial-and-error method. Varying conditions require corresponding variations in treatment, to be determined in each particular case. To apply a blanket recommendation to all highway conditions would provoke disaster as certainly as would the taking of a general cure-all for every known ailment. The following applies to the reinforced-concrete base as well as to the reinforced-concrete pavement.

First consider the country road. Service conditions and test roads have shown conclusively that the unsupported corner is the weakest spot in the slab. Next comes edge weakness, and then longitudinal weakness of slab when subjected to beam action. Provision can be made for edge weakness and the unsupported corner by thickening the edge or using the marginal bar. The bar should be turned across the pavement at the ends of the slab. Continuity of the slabs is secured by tying together the slab ends by 3-in. plain dowels, 4 ft. long, spaced 2 ft. on centers, with one end encased to allow them to slip or by interlocking. To strengthen against beam action a division of the roadway can be made by a central division plate with the addition of fixed dowels to hold the two slabs together, which increases the beam strength of the half slab four times that of the full slab.

Cracking caused largely by variable factors, cannot be prevented entirely with any amount of metal we can afford to use. The use of a wire fabric reinforcement however checks the extent of the cracks, distributes them and interlocks the different sections of the slab into a unit, so that it prevents the cracks from becoming a destructive factor and reduces maintenance to a minimum. For this result 35 to 65 lb. of metal per

100 sq.ft. has proved effective in actual service for periods exceeding five years. Service conditions have shown also that a fabric with a ratio of two to one or three to one laid longitudinally in the pavement gives good results in the divided slab but the general tendency is for an equal distribution of the reinforcement in all directions.

The city or village street presents a different problem from that of the country road. In the former the same edge and corner weakness is less likely to cause destruction both because of the loads are rarely so near the edge, and because the sidewalk, curb, gutter and storm drainage keep the subgrade covered and free from excessive moisture changes.

The treatment of the slab design depends on the way the pavement is divided from curb to curb and the width of the street. With good foundation conditions 6 in. would be a minimum of thickness with 42 lb. of metal per 100 sq.ft. of surface corresponding to a 6x6-in. spacing of No. 6 wire placed 2 in. below the surface, giving equal distribution in all directions. The slab ends should be tied together with dowels or by interlocking as for country roads. In addition to this, edges of the slabs subjected to traffic should be strengthened by the use of a marginal bar, thickened edge, or both, as the conditions require.

The advantages of the reinforced-concrete pavement are practical and obvious. Beyond them lies a deeper satisfaction. There are many tendencies in American life that are cheap, extravagant, pretentious and ugly, but there is a steadily increasing force of opinion demanding intensive work and sound value rather than extensive display. Working in harmony with that force, one is building for a better future. It is that hope that encourages us to look beyond supplying the immediate needs of transportation to promoting permanent improvement in highway work.

North-South Railway for Australia

A railway connecting the well-settled part of Australia along the south coast with the thinly settled section on the north coast, which has been projected at intervals for many years, is again under consideration. One purpose is to open certain inland sections for development, although part of the country is desert, but a secondary purpose is to develop northern ports and thus give shorter steamer routes to other countries. There is already a transcontinental telegraph line. From Port Darwin, on the north coast, in federal territory, a railway extends south to Katherine, about 200 mi. From Port Augusta, a line of the South Australian Government Rys., connected with the general railway system, extends north to Oodnadatta, 478 mi. Between these two lines there is a gap of about 1,000 mi., and the cost of a railway is estimated at \$68,500,000. Alternate routes have been proposed. A recent parliamentary committee has recommended a 150-mi. extension south from Katherine to Daly Waters and a 300-mi. extension as a light railway north from Oodnadatta to Alice Springs, which extensions are expected to be sufficient for several years. The lines are to be of 3½-ft. gage, laid with 60-lb. rails and probably with steel or concrete ties, if prices are reasonable, owing to the destruction of timber by white ants in the territory traversed.

Determining the Responsibility of Contractors

Determining His Acceptability as a Risk by a Reputable Surety Is Determining the Contractor's Responsibility

BY E. W. BUSH

Engineer, Aetna Casualty & Surety Co., New York, N. Y.

The committee on ethics of the Associated General Contractors, as noted in Engineering News-Record, Oct. 11, 1923, pp. 583 and 616, are studying the elements that determine the responsibility of a contractor. The question is of importance to engineers when receiving bids or awarding contracts to "the lowest responsible bidder," also to contractors when placing sub-contracts. We have asked E. W. Bush, engineer of the Aetna Casualty & Surety Co. to give us the viewpoint of the sureties on this subject. His reply follows.—EDITOR.

REPUTABLE sureties desire to write surety bonds on construction contracts for responsible contractors only, and the various bond-application forms, the financial-statement forms and the information schedules which are used have been prepared to disclose the contractor's responsibility. From the information received the surety forms an opinion of the client's responsibility and then, if the opinion is favorable, backs it with its financial strength and assumes the obligations of suretyship on the contract bonded. The underwriting of a contract is, as a matter of fact, the determining of the contractor's responsibility.

The Associated General Contractors' Committee has listed the following elements of responsibility:

1. Financial condition, bank credit and bank references.
2. Experience of person who will manage or direct the construction operations.
3. Plant available for the project.
4. Construction performance record.
5. Personal references for successful construction service.

The five elements listed are important, but, in general, they are not sufficient for sureties to act upon. Before being committed to the bond on important contracts they like the following additional facts, which, as explained later, are also elements in determining the desirability of the business, hence the "responsibility" of the contractor, for the project being considered.

6. Information regarding the proposed work, giving the kind of work, the location, the amount of the contract, the bid prices, and the other bids, if the bids have been opened. A copy of the contract documents is desired, also the names and addresses of the sub-contractors and the kind of work and amounts that will be awarded to them.

7. List of the other contracts on hand giving in regard to each the amount, kind, location, and approximate percentage completed, also whether or not each job is progressing satisfactorily and on a profitable basis.

Contract bonds are not liability insurance but are a form of credit because they increase the financial strength of the contractor to the owner by the amount of the bond. They are underwritten on much the same basis that a bank uses when extending a loan to the contractor—and for the same reasons. A bank meets

with losses but never makes a loan if it thinks there will be a loss; in the same way a surety never writes a bond if it thinks the contractor will not be able to complete the contract without the owner calling on the surety.

There is a limit to the amount of bonding credit a reputable surety will extend to every contractor just the same as there is a limit to his banking credit. Assuming that the contractor is honest, experienced in the kind of work considered, bears a good reputation, has adequate plant and organization, and the work is ordinary in character, this limit is fixed by the relationship existing between:

- (a) The contractor's net quick assets;
- (b) His total net worth; and
- (c) The volume of work to be performed. (The new work plus the incomplete portion of any contracts on hand.)

As a general underwriting rule, many reputable sureties like to see (a) not less than 10 per cent and (b) not less than 20 per cent of (c). With the same assumption regarding the contractor, the above makes a very good working rule to determine the contractor's responsibility in regard to any particular project or for work up to a certain aggregate amount.

Sureties frequently vary this underwriting rule depending on the size and nature of the work, the adequacy of the price, the previous success of the contractor in estimating and performing similar work, the profits being obtained on the other work on hand, whether or not the labor or material markets are stable and whether reinsurance can be obtained from other sureties. About the only underwriting rule that never changes is this one, namely, "The more favorable information the surety has about a contractor the greater will be his bonding credit." Reputable contractors and reputable sureties are both interested in eliminating the irresponsible bidder, and this will eventually be done if the best contractors will encourage the sureties to make a full investigation before writing the bond and they will give the sureties full information regarding their affairs. They can stand the investigation, whereas the irresponsible ones cannot.

A word is in order regarding financial statements because the net quick assets is an essential element in determining responsibility. The nature of the business requires contractors frequently to borrow large sums from banks in order to avoid a default and the amount that can quickly be raised is determined largely on the contractor's net quick assets. The quick assets consist of the cash, the earned accounts receivable and retained percentage, notes receivable, the securities possessed by the contractor, and the materials on hand that will go into contracts on hand. Against these are placed the notes and accounts payable and debts incurred to the date of the statement. Other assets of a slower nature would include real estate, materials that will not be required in contracts on hand, and plant, also any claims against others.

A mortgage against real estate is a slow liability, but while the plant is a slow asset a note given in payment for plant should be included in the quick liabilities because if it is not paid the contractor must go into the hands of a receiver. Money cannot be quickly raised on second mortgages nor on investments in speculative enterprises, and many notes receivable cannot be discounted. A contractor's plant is something he needs in his business, therefore he cannot sell it to finance his work. Banks, sureties, and others dealing with credits

are apt to scale down asset items which are obscure or of doubtful value, so it is desirable that a full explanation accompany each financial statement in order to have it appraised at its real worth.

The writer refers those interested in this subject of responsibility of contractors to the 1922 volume of the "Transactions of the American Society of Civil Engineers." E. A. St. John, vice-president of the National Surety Co., has an article on contract bonds, starting on page 1052; and E. C. Lunt, then vice-president of the Fidelity & Casualty Co., has a similar article starting on page 1058. F. S. Greene and H. S. Sisson have short articles on pages 1066 and 1068, respectively, that touch somewhat on this question, and the writer contributed a discussion to be found on page 1091.

Seven Plants Fabricate Steel For Chicago Building

Contract for 12,000 Tons Is Divided to Expedite Construction—Heavy Column Sections on Large Foundation Piers

DIVIDING the steel fabrication contracts among seven firms to insure rapidity of progress was the unusual step taken in the construction of the 32-story Straus Building now being erected for S. W. Straus & Co. at Michigan Ave. and Jackson Boulevard, Chicago. For 22 stories this building will be 172x161 ft. in plan, with a central light court about 56x50 above the fifth floor. Above the 22-story structure there will be a 10-story tower with a pyramidal roof surmounted by a 28-ft. sculptured group whose top will

FIG. 2—HEAVY COLUMN SECTIONS AND GRILLAGE

be about 475 ft. above the street level. The exterior finish will be of Bedford stone.

When the work was being planned early in the spring of 1923, it was found that it would be impossible to have any one plant fabricate the 12,000 tons of structural steel work within the required time so that the building would be ready for occupancy by May 1, 1924. To meet this condition, the owners divided this part of the work into sections and placed the contracts with seven fabricating plants in five states, each plant being required to have its material ready by a certain date. In this way, the general contractor is assured a steady supply of material so that the work can go forward as planned.

These divisional contracts were not placed on a tonnage basis but on a tier or floor basis, so that the structural details could be completed with a minimum of delay. Each tier embraces two stories, except that the third tier includes three stories. In order to insure systematic and steady progress it was essential that an erection program should be arranged and that each successive contract should be completed by a specified date. In the accompanying table is given the approximate tonnage of each steel fabrication contract, with the date for completion of delivery of material.

All the steel is furnished by the Inland Steel Co., Chicago, and the way in which the fabrication contracts for structural material are divided is shown by the following list: Grillage for footings, Lakeside Bridge & Steel Co., North Milwaukee, Wis. Steel slabs for column bases, Hansel-Elcock Co., Chicago. First tier, Morava Construction Co., Chicago. Second tier, Vanderkloot Steel Works, Chicago. Third tier, columns, spandrel and interior girders, Minneapolis Steel & Machinery Co., Minneapolis, Minn.; other girders, Lakeside Bridge & Steel Co.; vault, Duffin Iron Works, Chicago; floor beams, Morava Construction Co.; two 68-ton 53-ft. girders over the main entrance, Phoenix Bridge Co., Phoenixville, Pa. Fourth tier, columns and

FIG. 1—GRILLAGE FOR COLUMN IN STRAUS BUILDING, CHICAGO

Two courses of plate girders and top course of 1-beams with steel slab for column footing.

STEEL FABRICATION CONTRACTS FOR STRAUS BUILDING

Section	Material	Contractor	Approximate Tonnage	Date for Completing Delivery
Grillage	All.....	Lakeside Co.	540	Aug. 1
Slabs	All.....	Hansel-Elcock..	60	Aug. 1
1st tier	All.....	Morava	1,000	Aug. 10
2nd tier	All.....	Vanderkloot..	1,250	Aug. 20
3rd tier	Columns and girders	Minneapolis		
	Steel		1,000	Sept. 5
3rd tier	Girders.....	Lakeside.....	500	Sept. 5
3rd tier	Floor beams.....	Morava.....	300	Sept. 5
3rd tier	53-ft. girders.....	Phoenix.....	150	Sept. 5
3rd tier	Vanit.....	Duffin.....	150	Sept. 5
4th tier	Columns and girders	Kansas City		
	Struct.....		600	Sept. 15
4th tier	Floor beams.....	Morava.....	300	Sept. 15
5th tier	All.....	Vanderkloot..	850	Sept. 30
6th and 7th	All.....	Hansel-Elcock..	1,500	Oct. 5 to 15
8th to 12th	All.....	Morava.....	3,050	Oct. 20-Nov. 20
Tower	All.....	Vanderkloot..	650	Dec. 5
Total.....			11,900	

court spandrel girders, Kansas City Structural Steel Co., Kansas City, Mo.; floor beams, Morava Construction Co. Fifth tier, Vanderkloot Steel Works, Chicago. Sixth and seventh tiers, Hansel-Elcock Co., Chicago. Eighth to twelfth tiers, Morava Construction Co. Ten-story tower, Vanderkloot Steel Works.

Grillage for the column footings is composed of two or three courses of plate girders and I-beams, varying in size according to column loads. A complete grillage with steel slab for column footings is shown in Fig. 1. In the lower course the girders are 24 to 36 in. deep and in the second course they are 20 to 36 in. deep. When there is a third course, 15-in. I-beams are used. Steel slabs varying in thickness from 4 to 8 in. and of a size to suit the columns, with a maximum of 32 x 36 in., are placed on the grillage to support the first column sections, which are approximately 30 ft. in height. These bottom sections of the columns were placed before the interior excavation was made for sub-basement and lower sub-basement spaces. The columns are of I-section, built up of web and cover plates and four angles. Some of the bottom sections

are very heavy, as will be seen from Fig. 2. The bottom is planned to give a level bearing on the steel slab and has two angles bolted against the cover plates to hold the anchor bolts. Two steel guyed derricks with 123-ft. masts and 110-ft. booms are used in the steel erection.

Two other features of engineering interest in the construction of this building are the foundation piers, locally known as caissons, and the underpinning on the south and west sides of the site. The foundations consist of 78 concrete piers built in open wells sunk through the clay to bedrock at a maximum depth of 115 ft. below street level. Two of these piers are 11 ft. 9 in. in diameter and are said to be the largest ever built in Chicago foundation work. The concrete piers are about 60 ft. high, surmounted by the steel grillage and columns, as shown in Fig. 3.

Underpinning the old seven-story Leschin Building on the south side was particularly difficult, since the owners of the Straus Building were required to place piers on the property line to support a double party wall. Thus the wells had to be sunk under the existing wall. In the more general practice in cases of this kind, the piers are placed at a convenient distance from the property line and the wall is carried by cantilever girders. For the Leschin Building the underpinning was of the usual type, with transverse steel needle beams placed through the wall and supported by heavy timbers on the inside and outside of the building. These timbers in turn were supported by closely spaced screw jacks on timber blocking or cribbing. At the west end, some underpinning of the foundations of the Illinois Theater was necessary, but this was not difficult, particularly as an alley extends between the theater and the new building.

The new Straus Building is owned by the firm of S. W. Straus & Co., which will occupy the first six floors for its investment banking business. The architects are Graham, Anderson, Probst & White, Chicago. The Thompson-Starrett Co., Chicago, has the general contract. In direct charge of the construction are C. E. Harvey, superintendent for the architects, and N. J. Provost, superintendent for the general contractor.

Pier Construction on Rigolets Bridge

A correspondent reading the article entitled "Rigolets Bridge Built to Stand Hurricanes," in *Engineering News-Record*, Oct. 18, 1923, p. 626, was somewhat concerned about the possibility of damage in the concrete pier after the steel shell, in which the concrete piers were cast, rusts away. He felt that the steel angles bracing that shell would then be exposed to corrosion and being embedded in the concrete might set up forces which would break down the concrete on the face of the pier. Inquiry was directed to W. H. Courtenay, chief engineer of the Louisville & Nashville R.R., which built the bridge, and he replied that the whole of the 34-ft. diameter of these piers will be sunk below the bottom of the Rigolets and will be surrounded by sand and clay. The 28-ft. diameter shaft is built within concrete forms which are removed as the shaft is built up. This building up is done during the process of sinking. Upon completion of the sinking of these piers there will be no steel exposed to the action of the water except the steel of the 16-ft. diameter well shaft which has no angles entering the concrete.

FIG. 3—FOUNDATIONS FOR CHICAGO 32-STORY BUILDING

Many Engineering Graduates Are Needed in Industry

400,000 More Trained Executives Needed for Industries in 1930—Should Be Well Grounded in Fundamentals

THE FIELD of the nation's manufacturing activities has been surveyed by the National Industrial Conference Board with the idea of determining the needs of the next generation in order to suggest improvements in the educational plans for today. The results of its survey are given in its special report No. 25, on Engineering Education and American Industry.

In approaching this subject the board has attempted to answer three broad questions: (1) Do the industries of the United States need more or fewer engineers than the number now being graduated from engineering schools and colleges? (2) What kind of men do the industries require from the engineering schools and colleges, and what should be the nature of their education? (3) What are the responsibilities of the industry in this matter?

The report cites the fact that the expansion of industry during the past few decades has been accompanied by vastly increased complexities of industrial operations, and the grouping of greater numbers of workers in corporate units has placed upon employers an increased social responsibility towards their employees and towards the life and affairs of the community. All of these changes have created problems of human, social and political relationship in which industry and society as a whole have become increasingly dependent upon trained technical and administrative leaders. The present demand of American industry for men with effective educational training for such leadership may be fairly gaged by the present ratio of persons in positions of responsibility to the total number gainfully occupied in the United States. Of the 41,600,000 persons who were gainfully employed in 1920, less than 4 per cent planned the activities and directed the energies of the whole working force. This 4 per cent includes major officials, officers, superintendents, technical engineers, designers, draftsmen, inventors, architects, chemists, assayers, metallurgists and auditors, together with one-quarter of the number of foremen, overseers and inspectors in agriculture, mining, manufacture, instruction, trades, transportation and public service. The report assumes that three-quarters of the foremen, overseers and inspectors are not sufficiently distinguishable from the group of wage earners and workers to be included in the category of those who plan, supervise and administer the business of the nation. According to these figures, approximately 1,500,000 positions in the business structure of the United States must gradually be taken over by youths who have the ability and who shall have received training which will enable them to assume the responsibility of various forms of major and minor leadership.

Looking Into the Future—The board finds that if the records of the past fifty years can be taken as a criterion, the 1,500,000 will be increased to 1,900,000 in 1930. Its study shows how rapidly since 1870 the number of administrators, supervisors and technical experts has increased; in 1870 the number was only 170,000, or 1.25 per cent of the total number of persons

gainfully occupied. This increase has been particularly rapid since 1890, when the era of mass production began. The outstanding fact of this study is that the country must not only supply replacements for the 1,500,000 administrators and technical experts, but must also supply 400,000 more persons for positions of responsibility by 1930. The reason for this growth in the demand for experts and leaders lies in the change of methods by which industrial work is performed; methods of mass production greatly increase the amount of product per worker, but require a relative increase in the proportion of planners and administrators.

Talent Needed—Some idea of the kind of talent necessary for the industry can be obtained from the fact that 600,000 of the 1,500,000 administrators and technical experts in 1920 were engaged in manufacturing and mechanical industries, and it is estimated that 150,000 of the men and women classified as in professional service in 1920 are employed in or associated with these industries, so that a total of 750,000 persons, or approximately half of the total number in positions of responsibility, are connected with manufacturing and mechanical industries. A reclassification of these 750,000 persons indicates that they make up 5.79 per cent of the total of 13,000,000 persons engaged in manufacturing and mechanical industries, and that 4.51 per cent of the total are classified under owners of small establishments, superintendents of medium sized establishments, engineers, salesmen, and foremen. As the bulk of the men who rise to the chief executive positions of the medium sized and larger establishments work up from the lower group our engineering schools should provide education necessary for entrance into this group. Service in this group in competition with other college men and with the greater number who lack the advantage of higher education, but have the will to win, enables the engineering graduate to progress rapidly and to develop under observation of his chief. Contrary to the popular impression held by many young men, the positions in the upper groups are not attained by a short step from college but only through training in the groups at the bottom. Students and educators must realize that progress in this group requires sufficient time to get a proper insight into the methods of business, and the educators should co-operate with industrialists and aim to make the base groups adequate in every sense.

At present the demand for administrative talent is more pressing than for technical experts, but in the conditions of international competition now developing, research will be of the utmost importance. Success will lie in the improvement of technical processes, utilization of by-products, and reduction of waste as well as in better methods of production and distribution. The supervisory and administrative leaders in our industrial structure exceed the technical experts numerically, at least four to one, but no one should lose sight of the fact that both groups are essential and that in each there are positions of highest responsibility and honor.

The important thing is that the natural talent of each person be found and that the industrialists as well as the educators stimulate its development and use to the highest degree.

At the present time our engineering schools are turning out about 9,000 graduates per year, many of whom go into occupations outside of the manufacturing and

mechanical industries, so that it is difficult to tell how many act as replacements in the base group in these industries, but it is obvious that the number of replacements required and the number of new positions created annually constitute a demand far in excess of the number of graduates who desire such positions. Add to this the waste due to turnover of the personnel of the base group and to maladjustments and it constitutes a demand which, if it is to be supplied with proper material, will require improved methods of selection and training in schools and industries in order to cut down the time lost and the expense of getting men placed in their logical positions. This is a great educational problem.

The Educational Problem—In spite of the fact that many industrialists have concluded from their personal experience that the only effective industrial education is that obtained within the industry itself, the conference board believes that many more are coming to the realization that education in colleges and engineering schools and association with intelligent instructors and

FIG. 1—RELATION OF EDUCATIONAL SYSTEM TO WORKING POPULATION

students exercise a strong influence upon the capacity of young men to advance rapidly to positions of responsibility. Fig. 1 represents graphically the relation of our educational system to the working population and to the total population of the country. It should be noted that the data in this figure pertain to males only, whereas the previous data included both males and females; also that the figures showing totals are represented by the areas between the curves and the base lines.

According to the best information available to the conference board, there are about 350,000 living male graduates of colleges and engineering schools and only a part of them are in industrial, financial and commercial occupations. The total number of engineering

FIG. 2—CLASSIFICATION OF POSITIONS HELD BY ENGINEERING GRADUATES

graduates is about 70,000. The line representing these engineering graduates on Fig. 1 lies so close to the base line as to be hardly distinguishable, and the smallness of their proportion to the total gainfully occupied is apparent.

Since it is the boys and men between the ages of fifteen and twenty-five, both in schools and gainfully occupied, who come chiefly into the problem of correlation of industry and education, the problem requires the broadest survey of our educational system and its relation to the industrial situation. The phase of this problem which is naturally receiving most of the attention of the engineering schools, and which is the main consideration of the conference board's report, is illustrated as to numerical magnitude by the dark triangle at the bottom of Fig. 1, representing 51,908 students in the engineering courses of the colleges and technical schools in 1920. It is obvious that much depends on the method of selection and training applied to this group.

The Engineering School—Engineering education in the United States is now about 100 years old, and throughout this period of development the field of activity for engineering graduates has expanded continually and has shifted them more or less from the lines for which they were specifically prepared. This condition is well illustrated in Fig. 2. The figure is made up from a classification of the positions held by graduates from one of our engineering schools when they have been out of college from five to twenty-eight years. Graduates were classified in three main groups: (a) the men who are still in the field of engineering work studied in college; (b) the men doing engineering work in some other field than that studied; (c) the men who have shifted from strictly engineering work to executive or commercial activities. The latter group is subdivided by a dotted line to represent the number of those who went into activities totally dissociated from engineering.

One important question is as to how many of the shifts from engineering to non-technical pursuits have the nature of an advancement and how many were due to failure or a discovery that the graduate was better suited for some other activity. The report points out that after a swing toward greater specialization in undergraduate work in the engineering schools, there is now a general movement toward unification of courses. The colleges are now providing more and fuller courses in science, and the engineering schools by concentrating on the fundamentals rather than on technical training are following the traditions of the col-

leges, and it is becoming more evident that the schools are training young men to become fertile and exact thinkers, guided by common sense, who have a thorough knowledge of natural laws and the means for utilizing natural forces; and that the engineering schools now aim to produce not finished engineers but young men with great capacity for becoming engineers.

The National Industrial Conference Board summarizes the recommendations of sixty-eight industrial executives, thirteen railroad executives, four engineers, three educators, one editor, and six governmental officials as follows: That the method of selecting men for admission to colleges be improved; that the student be trained broadly and thoroughly in the fundamentals; that the colleges do more to stimulate initiative; that the instructors in technical subjects have more practical experience, and be selected for vision and high ideals; that the students be given practical training in industrial establishments either (a) by serving an apprenticeship before entering college, or (b) by industrial work during vacation, or (c) by supplementary industrial training after completing the theoretical course, or (d) by practical training in industry incidental with theoretical training in college.

The board calls attention to the fact that these recommendations apply broadly to the preparation for all branches of industry and that the industrialists are more interested in the general character and ability of their recruits than in the specific knowledge required in any particular industry. It also points out that while there is general agreement that engineering education should concentrate on fundamentals, there is a wide variation in the interpretation of "fundamentals."

The board emphasizes the fact that, although there is room in industry for more graduates than the engineering schools are now turning out, it is more important that a greater proportion of these young men be of high quality than that the total number be increased, and recommends that the requirements for admission should place a premium on intelligence, self-mastery, resourcefulness, courage, vision, open-mindedness, patience, resistance, critical judgment, integrity, and other elements of character as well as the knowledge pre-requisite to the college course.

Responsibility of Industry—The report points out that every industrial corporation of any considerable size must have a well thought out educational policy for the development of its interests, and that such a policy involves a measure of assistance to the engineering schools and colleges in the development of their courses of study and in providing opportunities for practical experience for the students. Such a policy involves adequate methods of training within the industry. As many engineering schools are rich in buildings and equipment but need help in improving the effectiveness of their teaching forces, industrialists can assist in finding and developing men for this service and can increase the esteem in which educators are held. They can also provide the opportunity for instructors to maintain contact with the industry and its needs and to become acquainted with the latest industrial methods and practices. They can also assist by devising ways and means of adequately testing the boys in preparatory schools and in making clear to the educators how young men with different types of mind and different kinds of training fit into the industrial order.

Through the Reclamation Country

By F. E. Schmitt

THIS is the seventh of the series of letters written by Mr. Schmitt during a journey recently made through the West in which he visited irrigation projects, studied developments, and interviewed builders, operators and settlers, in order to present to our readers the actualities of reclamation as revealed to an unprejudiced investigator.

The series of letters began in the issue of October 4.

Calexico, Calif.

SEEING THE great Imperial Valley, which is hardly more than half farmed although nearly a quarter century old—brings forcibly to mind two common but erroneous assumptions, (1) that the federal reclamation projects are unsuccessful, and (2) that this is due to their having been handled less efficiently than other irrigation projects. The fact of the matter is that the reclamation projects are fully as successful as the others. (I am going to call these others private projects, regardless of whether they operate as corporations or as quasi-municipal districts.)

Irrigation development takes time. But even though the reclamation projects are younger than the Imperial district, their condition shows that taken all together they are equally successful. This district has the same troubles in respect to settlement, speculative ownership, failures, insufficiently high productivity, waterlogging and drainage, and complaint over high operating cost. Yet no one can call the Imperial district unsuccessful. It is a busy, peaceful farming community that manages to pay its taxes and its bonds; and its 55,000 population, 800,000 acres of area on both sides of the Mexican line, 500,000 acres of actually cultivated area and \$50,000,000 annual production make it the most notable single agricultural feature of the Southwest. If it had been built as a federal reclamation project it would be no less successful than it is, I am sure—and anyone can convince himself of this by looking at the much less favored but more maligned Newlands project. But if the Imperial were a federal project its present engineer-manager would probably be denounced along with the whole engineering force of the Reclamation Service as an incompetent, responsible for running it into the ground, and the politician momentarily at the head of the Department would send a lame-duck product of state politics to direct him.

An Interview With J. C. Wheelon—That private irrigation projects are subject to almost precisely the same conditions as the federal projects was made very clear in an instructive interview given me a couple of weeks ago by John C. Wheelon, the veteran engineer who is general manager of the Twin Falls Canal Co., the operating organization of the South Side Twin Falls district in Idaho (noted among all northern projects as a prominent success). Mr. Wheelon said:

"We have just as many worries here as they do on the reclamation projects. Our people are the same kind as theirs, and settlers come to our project without any money just as they do to the reclamation projects.

"We started out with the idea of getting the successful renter, the man who wanted to become independent.

Under this plan settlement was so slow that we moved the line of our main canal downhill from one to four miles. But soon afterward the plan of settlement was changed, selection of settlers being eliminated; then the project settled up so fast that we built an upper canal on the original location in addition, a big increase in investment.

"The men that came were chiefly the failures elsewhere, middle-aged men, men who were fighting in the last ditch. We had the same experience in the Bear River valley; that project, now nearly thirty years old, is not yet out of debt, just getting on its feet. There as well as here it took three crops of settlers to make the project a success. It's not much different elsewhere, regardless of irrigation or natural supply of water; they say that in Kansas it took ten years to raise the first crop of corn, and sixty years to make it the garden spot of America, and Kansas isn't out of debt yet.

"Not all of our original settlers are here, by a good deal. Among those who are still here, there are some who came with capital to start in—as for instance, one family that came with \$10,000—and have lost it all and may soon have to walk out. Others came broke and made a success. But not all that have left the project were failures; some Illinois men came here who were good farmers there and became good farmers here, and later on they sold out at a good profit.

"Our irrigation system cost about \$26 to \$27 per acre to build; we charged \$26, a figure fixed in the beginning when we thought it would be ample to cover the cost. Our losses were made up on townsite lands, however. The low cost of the project is due to the remarkably favorable topography and to the ingenuity of the layout, which took full advantage of the topography. No drainage cost is included, as drainage was not done by the land company but is being carried out by the operating company in conjunction with the land owner, on a division of work which puts about 90 per cent of the cost on the company and 10 per cent on the farmer. But, despite the low cost, if this had been a government project there would have been the same amount of complaint howling that the reclamation projects get. Little politicians are the bane of reclamation.

"Irrigation farming looks pretty when you're traveling through it; but when you've got to live with it, for thirty years, it's different. The difficulties and hardships show up more strongly. It is not the same as farming in the East. When you come on to irrigation you find that it takes a better mechanic, a higher-class farmer, to handle the work successfully.

"That is why a weeding-out process is inevitable. Proper leveling of the land before the settlers came, or leveling and cultivating, might eliminate one of the three crops of settlers. But if 90 per cent of those who go into any occupation make failures, how can you expect 100 per cent to succeed in fighting the battle of the sagebrush desert?"

Private Irrigation—It may be worth while in this connection to remind the Easterner, who is apt to think of reclamation as being the whole of Western irrigation, that something over 20,000,000 acres is irrigated, west of the Missouri River, and only one-tenth of this is federal reclamation. Reclamation is 21 years old, but modern irrigation in these western valleys goes back three times as far, not counting the prehistoric irriga-

tion in the Southwest revealed by remains of ancient canal systems, perhaps built in very early Indian days. With respect to success, private irrigation has less authority than its age and size would suggest, for systematic procedure (other than simple group co-operation) began less than 40 years ago, with the famous Wright Act of California and the later Carey Act of Congress. Further, the financial side of irrigation has been in an unhappy tangle until quite recent years. It shows so consistent a record of failure that the blackest picture ever painted of federal reclamation would by comparison shine with the brightness of success. Disappointments and financial losses without number have proved that irrigation is a very dubious field for money-making enterprise.

Irrigation as an Investment—One man's statement of the case, "As an investment, irrigation is simply not in it," has been widely endorsed. Nevertheless, a generation ago, capitalists saw big profits in irrigation development, and a few bond houses thought there were opportunities for making money by selling irrigation bonds. One or two successes were made, but then the bond market gave out, land sales and settlement decreased, and the industry ran onto the rocks. These troubles of the promoters (and of investors in bonds, who lost most of their money) delayed the development of stable systems of operation, but do not affect present-day comparisons of private with federal projects. Thus, the Imperial district here is operating with complete success, though the California Development Co., which promoted it in the early days, went bankrupt; and the same is true of many wholly successful irrigation districts not only in this state but throughout the West, where the records show case after case of a 20 to 80 per cent loss of the original bond investors through non-payment or a scaling down of the bonds, though at the present time the operation of most of these districts is nearly as smooth and uneventful as the operation of a city water system.

Since irrigation conditions necessarily differ much, comparisons can be made to show almost anything. But closely adjoining projects are usually fairly comparable. Such a case can be found at the North Platte reclamation project, near Mitchell, Neb., where the federal project covers the upper part of the valley slopes and has a rather costly reservoir and canal system, while the lower slopes are occupied by private ditch systems much cheaper and simpler to build. Other cases occur in the Uncompahgre River valley, near Montrose, and in the Colorado River valley near Grand Junction, Colo. (Grand Valley project); and it may be noted that in the latter instance one of the private projects is rated as the most successful irrigation district in the state. Equally good comparisons can be made in the Snake River valley in Idaho, where alongside the federal Minidoka project there is much private irrigation, including the South Side Twin Falls project.

Reclamation Successful—Facts and figures in cases of this kind show clearly that: (1) federal projects compare favorably with private projects in first cost; (2) federal projects have an ample and dependable water supply, while private projects are apt to have an inadequate supply; (3) federal projects are well planned and well built, usually much better than private projects; (4) if there is any difference in fairness and efficiency of operation and care of maintenance, it is in

favor of the federal projects; (5) the operating cost of federal projects is lower than that of private projects.

Summarized, these points mean emphatically that reclamation has been done remarkably well and that the Reclamation Service has made a thorough-going operating success.

This latter is in large part due to the engineer operators—the project managers and the engineering organization of which they form a part. But the headless talk that has been coming out of the Interior Department to the effect that engineers are not fit to operate irrigation districts is shown to be frivolous not only by the performance on the projects themselves, but also by such facts as that engineers manage the three most remarkable and probably also most successful districts in the country—the Imperial Valley in California, the South Side Twin Falls in Idaho, and the Salt River Valley in Arizona.

As to First Cost—The five points above stated give opportunity for any quantity of discussion and dispute. Without undertaking to prove them here, I want to cite one or two illustrative cases. A good comparison of first cost may be made on the North Platte project, where the Tri-State ditch, (owned by the Farmers Irrigation District, originally a corporation project) and the reclamation or Interstate ditch, much farther up the hillside, are parallel; the Tri-State ditch system, without storage and *without laterals*, cost \$42.50 per acre, while the government ditch, with a much longer canal system, much more scattered land, and a costly storage reservoir, and lateral canals to each farm, cost \$71 per acre. Similarly, the South Side Twin Falls project, with a remarkably favorable topography and layout, cost \$27 per acre, without storage; the North Side Minidoka project, less favorably located, cost \$42 per acre with storage, and this includes a considerable item for drainage, while at Twin Falls the drainage cost is being met out of operation charges.

Reclamation moneys were spent with exceptional efficiency and honesty, and the farmers' spokesmen who charge that the project costs are too high would learn much, if they cared to, by examining the costs of private projects in their neighborhood, including the cost of making up for premature decay or the short life of fantastic hillside flume systems—some of which the Reclamation Service has had to take over in order to save the farmers from utter ruin even after the outside investors had given up their own investment. It has to be considered also that the low lands, of best quality and easy to irrigate, were taken up before the government came into the field, so that reclamation in most cases deals with the costly, uninviting and sometimes decidedly forbidding propositions, while private development always is concerned with inherently promising cases. Also, that reclamation in all cases is based on a supply assured by very costly dam work when necessary, while private development is usually content to take chances with a doubtful supply, in order to save cost. As to needlessly high-grade work, I had an engineer tell me that the Service made a mistake in building concrete-lined canals where clay lining would have done; but a water users' manager complained to me that the Service had not built well enough, so that the district now is "practically reconstructing the whole system," an absurd exaggeration of normal maintenance

needs which is valuable only as neutralizing the statement just preceding.

Operating Costs—Operating costs are the reclamation farmer's special bugbear. He says they are too high and blames this fact on the high overhead of the Service. "We have to support those offices in Denver and Washington." The facts are against the farmer.

He gets cheaper service in operation and maintenance than the private-project farmer. To take a case: the Grand Valley project, in Colorado, has an operation and maintenance (O & M) charge of \$0.75 per acre-foot or for 3 acre-ft. per season a total of \$2.25 per acre. The much cheaper private development on the lower valley slopes, the Grand Valley Irrigation Co., has an annual O & M charge of about \$1 per acre; but this system operates only the main canals, which is less than half the total O & M cost. The Palisade Irrigation District, close by, has an O & M charge of \$1.75 to \$2 per acre (leaving out interest and sinking fund). Three other districts adjoining (Mesa County, Orchard Mesa and East Palisade) have charges respectively of \$3.20 to \$4.80, \$6 to \$8.50, and \$18 to \$27, the latter case being a very small district (646 acres total) and having heavy replacements to make out of its operating income. Similar comparisons, each qualified by taking note of many special conditions, can be made anywhere; and even a comparison of reclamation costs with exceptionally low private costs, as Minidoka and Twin Falls (North Side Minidoka, gravity supply, operated by water users, \$1.90 per acre; South Side Minidoka, high-lift pumping supply, operated by government, \$1.95; North Side Twin Falls, private, \$1.10; South Side Twin Falls, private, \$1.12 for O & M excluding drainage or interest) strengthens rather than weakens the comparison. To make the case still more definite, the alleged high overhead of the Reclamation Service is in fact a lower percentage than that of private operation.

One further point may be made in favor of the success of the Reclamation Service work. An active antagonist of the Service, a water users' official who has declared himself an enemy of engineer operation of the Service and who is pretty constantly engaged in guerrilla warfare with it, in writing to another water users' official who had asked for advice gives the following pretty testimonial to the Service: "I do not know of any organization more competent to construct drainage and flood protection works than the Reclamation Service. . . . Our experience is that it is able to do construction drainage work far cheaper than private contract; we have tested the matter very carefully. . . . I have never heard of any graft or charges of graft. In my personal opinion the Service is the most efficiently conducted department of our government, as well as the most economical." These remarks were written prior to Secretary Work's entrance upon the scene.

Second Trent River Lock Completed

The second of the four locks being built to improve the Trent River in England has been completed at Stoke Bardolph. The plant is to render the Trent navigable the year around for large type barges as far as Nottingham. The first lock is at Holme Pierrepont. It was completed a year ago. The other locks are at Gunthorpe and Hazelford, and work is well advanced.

Federal Land Reclamation: A National Problem

4. Twenty Years of Reclamation

By F. H. NEWELL

Formerly Director, U. S. Reclamation Service

The Fourth of a Series of Articles on the History and Performance of the Great Government Adventure in Irrigation of the Arid Lands of the West.

TWO DECADES in the life of a nation are relatively short, yet these last two decades have been so crowded with experiments in governmental ownership and operation of public utilities of various kinds that they afford illustrations of the trend of governmental affairs greater than during the preceding century. To students of political and social science there are perhaps no more interesting examples of the strength and weakness of government ownership than are afforded by the history of the Reclamation Service since its inception in 1902 to its conclusion as a Service in 1923. Advocates or opponents of governmental interference in local affairs find many excellent illustrations of good or bad conditions. On the whole it must be admitted that whatever theory may be urged, the material results are highly commendable and reflect credit upon the men who initiated this work and placed it upon a high plane physically and morally.

During the twenty-one years of existence there have been created, as stated in a previous article, opportunities for 33,000 self-supporting small homes, affording a livelihood for at least 150,000 people. The gross crop production has been \$50,000,000 per year and over. The homes thus created have a value to the community and to the nation out of proportion to their mere number because these are located in what were previously barren wastes, now converted into highly productive oases. By their presence they make possible a development of many industries which could not otherwise have existed and they have raised the general standard of comfort and prosperity of the more sparsely settled states.

In all these undertakings under the Reclamation Service, perhaps the most interesting are those which have had to do with the human factors as contrasted with the purely physical. These include the influence or effect of the work on social institutions, and upon the opinions of men regarding governmental affairs. In one sense, the work of the Reclamation Service has been a practical exemplification of state socialism in that the government has used its own funds and employed its own servants to build works for the benefit of its citizens and has operated these works for many years at its own expense, losing the interest on the investment.

The men who advocated and organized the Reclamation Service believed implicitly that it was practicable to conduct work of this kind under a government organization and with an efficiency comparable to that of a well organized corporation. They did demonstrate this fact. The outcome shows that with a nearly ideal organization and with a high degree of efficiency it has been possible to achieve nearly ideal results wherever the mass of the people concerned have been endowed with the ideal degree of energy and ability. In proportion, however, as the land owners under the

reclamation projects have been lacking in ability, strength, experience, good health and other essential qualifications, to that degree the results have fallen below the standards set.

As previously stated, wherever good farmers have chosen good land under the reclamation projects, and have practiced a good system of farming adapted to the climate and markets, there the results have been such as have justified the most optimistic statements. Where, however, the inexperienced or poor farmer has been unsuited to his method of farming and so handled the land and water that the soil has deteriorated in productivity, and especially where he has become discouraged and moved to town, renting his land to itinerant tenants, there the results are disappointing and can be pointed to as showing the ineffectiveness of governmental control.

Comparison with Private Irrigation

It is to be noted that the work by the government in reclaiming lands introduced few novel features other than those which grew out of the fact that the operations were conducted by government officials, working under the limitations imposed by a century of accumulated rules and regulations. There had already been built works bringing water to over ten million acres of land at the time the reclamation act went into effect. Most of these earlier works were extremely simple because the easier enterprises were naturally taken up first. There remained for the government the more difficult—in fact, it may be said that in 1902 investors had come to learn through bitter experience that the building of reclamation works, especially those involving water storage and the settlement of the land, could not be made a matter of profit.

By 1900 all the larger private or corporate irrigation enterprises, with hardly an exception, had gone into bankruptcy or had been reorganized with almost complete loss of the original investment. The strong argument for the government's taking up this important work was that, under private or corporate auspices, it had not been and could not be put upon the basis of earning 6 per cent interest on the investment, much less of obtaining a profit. Thus land reclamation and settlement in the West was practically at a standstill and it looked as though the West would remain largely undeveloped unless some way was found of inducing the government to assume the load and to lose the interest on the investment. It was argued that such loss would be made up, or more than compensated for, by the indirect gains which necessarily come to the community, to the state, and to the government itself through the creation of homes on the land.

The assertion is made that the government, that the whole body of taxpayers, can well afford to lose the interest on its investment for at least 10 years, or,

to put it in another way, can afford to give this as a bonus or subsidy to the land owners under the projects as compensation in part to them of the hardships and uncertainties of pioneering.

In the matter of the original investment in reclamation works and in their economical construction, there is little but commendation to be given. This much can be claimed for governmental ownership, that in expenditure of funds for construction it is possible for the employees of the government to reach and maintain a high degree of efficiency. When, however, we turn to the other side, that of operation and maintenance, a different story may be told. Here it is not a question of expenditure of moneys to secure a certain definite result, planned out in advance; the large and crucial factor is not the economy of use of materials and forces but it is the effectiveness of dealing with large numbers of persons, individually and collectively, in matters pertaining to their most intimate personal affairs. Here governmental methods have not yet been developed to a point where it can be claimed that a degree of efficiency can be secured at all comparable to that of private control. Here is where the government official is seriously handicapped. He cannot exercise the same discretion in dealing with voters that he can when, as an employee of a corporation, he is doing business with individuals. Here is what at present seems to be the insuperable obstacle to success in governmental operation, and here is where the reclamation laws should be so amended as to require that the reclamation works, when built, shall be put under the control, at the earliest practicable date, of responsible well organized land owners of the community whose existence depends upon the maintenance and operation of these for all time to come.

Problems of Reclamation Service

Legislative Difficulties—While there has been a progressive improvement or evolution in economy and efficiency in engineering and industrial or business details, there has been under congressional control a lack of forethought, a failure to meet future needs, that tends to frustrate the object of the law. In each recent Congress, engrossed in other matters, a few interested men have struggled, against the general indifference, to secure certain personally important objects, often incongruous with the making of homes on the land. On no one leader has fallen the mantle of the late Senator Newlands; none has voiced his inspirations toward achievements of country-wide benefit.

The most conspicuous of these activities urged before Congress have had to do with the carrying out of the larger objects of the original reclamation act in home-making, but more with the attempts to secure minor adjustments to meet the demands of individuals or groups of land owners who have not been able to utilize their lands in such way as to produce average results in the way of crops. Under private projects the owners or managers necessarily possess full power and authority to deal with such individual land owners who are found to be unfortunate or are unqualified as farmers. Of necessity they must make individual exceptions and adjustments, helping one man to let go and stimulating or encouraging another man in accordance with his individual capacities. The agent of the government, however, cannot exercise anything like the same degree of discretion, even though he may be

better qualified to do so. He must treat all alike and must endeavor to carry out the requirements of law whether these are applicable or not. What really results is that the ultimate decision by the "powers that be" is that in order not to oppress any one citizen, all others who might make payments or comply with general conditions are excused from so doing.

Thus, due to the attempt to meet individual difficulties, there have been passed in succession a number of general relief acts, the most notable of which extends the time of payment of the capital investment from ten years without interest to twenty years without interest. Now the proposition is still further to extend this time to forty years, also without interest. No community or no country has ever granted conditions as liberal as these nor has imposed upon other taxpayers the corresponding burden in the way of subsidy granted indirectly to land owners under reclamation projects. This bonus or subsidy given by Congress and levied upon the general taxpayers has been estimated at about \$6,000,000 per year. This is figured on the assumption that for reclamation purposes \$140,000,000 has been kept out of the treasury. An equivalent amount is being borrowed for purposes of the government on which 4½ per cent is being paid. Many taxpayers are beginning to ask whether this is fair in consideration of the fact that whenever land owners, other than those on reclamation projects, secure any loan directly or indirectly from the government, such as through the federal farm loan banks, they are required to pay 5½ per cent interest plus 1 per cent amortization. They are asking why the landowners on reclamation projects, who claim a larger average crop production than other parts of the country, should be thus favored.

Imperfect Policies—Congressional control, or perhaps more properly, lack of a definite policy established by Congress, has led to the taking up of an infinite number of minor details which might better be left to local enterprise. It has already been pointed out that the proponents of the act did not contemplate applying it to the smaller distributaries or to the tens of thousands of small structures which, on private projects, up to that time had been left to the individual land owners. Neither has Congress expressly authorized or forbidden the leveling of the land and getting the farm into such condition that the newcomer might get to work to produce a crop.

There are still two distinct schools of thought in reclamation and settlement policies: one, the older, contends that the best results will ultimately be attained if the government confines its efforts to building the larger structures, such as can not be built by private enterprise and leaves to the individuals, or rather to the community or to the state, all of the matters of roads, distributing systems, leveling the ground, and getting ready for immediate cultivation of the land. The advocates of the other course point out the self-evident fact that the quicker the pioneer can get his farm into good condition the better for him and for the community at large. This is true if he is qualified to utilize these advantages, but if not then there is a question as to whether the hard struggle of the pioneers in developing a farm, each man for himself, is not an essential prerequisite to success through the early elimination of the unfit. Much can be said on both sides of the question and usually the

manager of the reclamation project, where most has been done to facilitate settlement, believes that the other course would have been better and vice versa. Neither is satisfied with the actual results.

The reasons for success or failure lie not so much in climate, soil, or markets, but rather in the character of the landowner, his experience, strength, health, and especially the "will to win," or possession of qualities which distinguish the pioneer. Unfortunately, the law does not permit any selection of the men, and their families, who are to enjoy the bounty of the government. The theory of the law is that the old rule is to be followed, "first come, first served." It makes no difference whether the applicant is young or old, strong or weak, single, married, or widowed, a hopeless invalid, or a giant in strength, he or she is allowed to take the land, if available. In the case of two or more applicants for the same farm the matter is determined by lot and not by any question of merit or ability other than that ex-service men and their widows are given a preference.

Results of this Method—Results of this haphazard method have been the same as if the army or an industrial organization should be recruited in the same way. The strong husky laborer might get a place as copyist and the weak, frail widow the job of furnaceman, the officers being selected by lottery. The process of elimination which must follow any such course has been heartbreaking and has tried the nerves of every one connected with the Reclamation Service. Each governmental employee has felt a certain personal responsibility in these matters. If he were free to exercise his judgment and to act as could the employee of a private concern, he might greatly help or at least he could prevent many of these people from getting into difficulty, but as an employee of the government he must of necessity stand by, report conditions, and wait for instructions.

The worst results, as above noted, have come not from physical conditions of soil, climate or markets, but from the lack of adaptability of the land owner and especially of his family to the peculiar conditions on each piece of land. The good farmer, the man of experience, on coming to a project, has not been willing to spend his time or money on land of inferior grade. The inexperienced man coming perhaps from the city, and knowing nothing regarding soil, has seized upon every available acre, has importuned the man in charge to include lands obviously unfit, and because of his inexperience has not been able to bring these lands up to a high degree of fertility, but on the contrary has allowed them to deteriorate.

It should not be inferred, however, that it is possible in advance to judge unerringly of the value of soils and of the effect of water upon the soil. It is only within a few years that the notable work of Carl S. Scofield and others has begun to reveal some of these mysteries of soil becoming "worn out." He has shown that as a broad generalization, "soft waters make land hard, and hard waters make land soft" or tillable. He has also brought out more strongly than was before assumed, that while in most cases excessive use of water is injurious, in some cases it is absolutely necessary in order to wash out the accumulated salts. It is not proper to attribute any blame or want of judgment either to government officials or to the settlers

in many of the cases where lands have deteriorated or become less productive.

The error which has prevailed through all private enterprises and has affected government work as well, was that of assuming that the large areas of reclaimed land could and would be settled upon immediately. Experience has shown that an agricultural community, like a tree, cannot spring into full bearing at once. Years of slow growth are essential; especially where there has been no selection of the settlers there must be a rapid turnover. Many families must come and go before there is a fairly complete adaptation to local surroundings.

Taking the United States as a whole, including new and old farming localities, there has been a turnover during the last year of 6 per cent in farm ownership and 27 per cent in tenancy. If the reclamation projects were on the same average with that for the rest of the country, there should have been a complete change in ownership during the past sixteen years. This normal change in part has been retarded by the well meaning attempt on the part of Congress and of the executives to induce the early settlers to remain by granting easier and easier terms of payment. As a matter of fact, as shown by experience on similar private enterprises, it is a matter not only of good business but of fair dealing to enable the rapid turnover in land ownership which ultimately results in getting people who are better qualified farmers.

These imperfections or errors have resulted in a stimulation of speculation. This in turn has been followed by tenancy and the accompanying evil of soil deterioration. Speculation has been promoted by the easy terms of payment. Many a man controlling a piece of land given away on condition of settlement and furnished with water at cost at government expense, and without interest payment, has preferred to hold on to this piece of land. Perhaps his wife has a similar farm; also his son and daughter. He may thus in the name of others control several farm units. He prefers to move to town and try to rent these and gain a profit through the increase in land prices. Some have succeeded. The majority have failed. The blame, if any there be, is not that of the management, but rather of the well-intentioned members of Congress who have urged more and more lenient terms in the law regarding repayment of debts owed to the government.

Irrigation Troubles—When the government went into the business of reclamation of lands by irrigation, there was little in the way of accurate facts recorded regarding irrigation methods. It was only after the government had embarked upon this enterprise that the experts of the Department of Agriculture began to give out the results of their observations. The owners and operators of private projects were unwilling to admit the existence of certain difficulties, believing that these were local in character, but as time went on and they became better acquainted with the difficulties, more and more these were brought to the front, especially as the methods of remedying the troubles became apparent. For example, the swamping of areas under irrigation was known, but the explanation generally given was that gross carelessness had been used; careful observation demonstrated that even with the most economical handling of water there has

been some swamping of cultivated fields, requiring the construction of drains, and that thousands of acres have deteriorated, usually with the appearance of alkali on the surface, but occasionally without any apparent cause.

Enough was known about the necessity of drainage to justify the preparation of plans for drains from the very outset of governmental reclamation. Some of the main line drains were built, others were projected with the thought that the land owners would build these at their own expense, as the need developed through the complete settling up of the country. Experience showed, however, that it is not possible in advance to lay out an economical drainage system because it is impossible to ascertain the texture of the underlying soils or to predict with any considerable degree of success what effect the percolating waters will have on this complicated texture. Thus drains built in advance of irrigation sometimes have been found to be wholly ineffective. In other places, where the underground sands or gravels seemed to indicate that drainage would never be required there, it has been necessary after a few years to construct large drainage works. Many of these matters are covered, as above stated, in the review of the subject by Scofield.

Observation also has changed somewhat radically the conceptions as regards the so-called duty of water, that is the amount of water required to furnish adequate moisture to a given area. Popularly it is assumed that a cubic foot of water flowing continuously throughout the irrigation season will furnish adequate water for one hundred acres. In other words the water duty is expressed as one hundred. A more accurate way of setting the duty is in terms of the total amount of water applied to the land, that is, thirty inches in depth during the irrigation season. For many years the remedy suggested for every evil was to increase the duty, that is, to increase the number of acres which could be irrigated with a given quantity of water, but, as above stated, scientific research has shown that this is not always a safe rule.

Political Management and Land Speculation—During the first decade, following 1902, the control of affairs was under men who drew up the reclamation act and fought for it, who had the vision of service. Then came new men, who had not argued for these great objectives, who viewed the law simply as an established fact, as an opportunity to stimulate local business immediately by spending federal funds, in contrast with the original ideals of future permanent benefits. There was a reaction from idealism to so-called practical considerations. Liberal concessions were made to the speculative interests, to the lawyers, merchants, tradesmen, or mechanics, who had acquired one or more pieces of government reclaimed land, ostensibly for a future home, but more directly in the hope of selling at a profit. These landowners, living in town, rented their farms. Tenancy rapidly increased, accompanied by "mining" the soil and crop decline. Speculation in land, the desire to capitalize the future, to get the unearned increment of value, is a strong temptation to all citizens. The speculative element is made up of wide-awake men, keen in local affairs, usually more active than the man out on a farm, who is busy with crops and livestock.

It is true that the *bona fide* homemaker does com-

plain that the non-resident land owner is favored, that itinerant tenants are not desirable neighbors, that the neglected fields—of the speculative owners—are infected with plant and insect pests, that roads and schools cannot be kept up—but his voice is relatively feeble. The fact that the "town farmer" has greater influence in getting more favorable terms of payment, still further increases the speculative tendency. In short, it is the relatively well organized minority, the men who have the time and inclination for discussion and letter writing, who make the greatest impression on the law-makers.

The attitude of the states in which the federal reclamation projects have been built has been rather favorable to speculation. The state lands, within the projects, in many instances have been held out of use for years and at prices which are so high that purchasers are wary. The conditions of sale of state lands have been such as to further speculative holdings instead of enforcing the requirement of actual cultivation and settlement. The highest result in land reclamation and settlement can be attained only when the public demands that state officials co-operate fully in these matters and maintain a higher ideal of the use of the state lands in making homes as contrasted with making money.

Borrowing by Farmers—The greatest difficulty in connection with the successful operation of any reclamation project, private or public, is that connected with the financing of the farmers. Most of these take up a new farm on cheap land largely because they do not have adequate capital to get a start elsewhere. Few have enough capital or credit to successfully handle even a small irrigated tract. Many would-be-farmers forget that farming is a capitalistic enterprise and that a certain amount of equipment is needed even by the tenant farmer. The owner must invest a large amount of money directly or indirectly in securing a shelter for his family and for his animals and in procuring the tools, seed, and other essentials.

The federal government does not lend money directly to these pioneers nor has the state done so except in a few instances. Most of the money or credit needed must be had from relatives, friends, or from local banks. The interest charge in these new communities is high, rarely if ever less than 8 per cent, more often 10 per cent or even 12, when commissions are added. This makes a load which it is almost impossible for the pioneer to carry unless he has some money of his own or is prepared to endure privations or even hardships.

It is true that the government indirectly furnishes some credit in that it has in effect loaned a considerable amount of money to the land owner, with no interest; that is to say, it has invested say \$60 per acre in his eighty-acre farm or \$4,800, without interest. The possession of this farm on which he may have paid nothing enables the owner to borrow considerable amounts of money, but on this he must pay a heavy rate of interest.

On top of this heavy interest charge are the large taxes which have been incurred in every new community for roads, school houses, bridges, county buildings, and all the improvements equaling or exceeding those of old communities in the east. The pioneers are trying to do in ten years what their forefathers did in a hundred and are correspondingly loaded with debt

such as can be paid only by exceptional crop conditions.

Landlordism—The ultimate object of the Reclamation Act, being the production of small self-producing farm homes, it is obvious that its success must be measured by the number of these contented homes rather than by great works, no matter how economically or effectively these have been built. The most important item then in any review of twenty years of reclamation is that relating to the number and proportion of successful homemakers.

Taking all of the farm units which have been irrigated or furnished with water by the use of the reclamation fund, it appears (Fig. 1) that 73 per cent may be classed as successful; that is, the family of the owner apparently has been supported by the products from the soil, which without irrigation (effected by the government works) would have been prac-

sometimes three or more, the intent of the law being evaded by holding these in the name of the wife, child, or other relative.

These owners of two farms, who are rated as successful, comprise 10 per cent of the total, and those holding three or more farms, which they are cultivating themselves, comprise three per cent.

Of the unsuccessful landowners, the greater part, 11 per cent of all farms, are the people who are not living on their single farm, but are renting it. Other unsuccessful owners have two, three, or more farms, the rent from which, however, is not adequate to pay the interest, taxes, and other dues, and yield an income adequate for their support.

The reasons for the spread of landlordism are by no means simple, most of them arising from the easy terms of repayment and consequent inflation of land prices. Other causes lie in the fact that many of the people who have acquired lands under reclamation projects have found the inconvenience of country life too severe. They desire to live in town on account of the schools or of the conditions of employment of one or another member of the family. They find that the "lure of the white lights" is too much for the younger members or the earnings in industry are greater than those from the farm. It is perfectly proper that they should move to town but the point is made that the government has practically loaned the money, invested in reclamation, to the land owner for the purpose of enabling him to secure a home on the land; if he does not wish to live in this home, then in fairness he should permit some other owner to have possession rather than hold the land out of use or as a source of income through rents derived from a tenant or from the labor of a hired man.

Conditions Affecting Success of Reclamation

Degrees of Productivity—One of the alarming conditions on the reclamation projects has been the tendency toward decrease of productivity commonly known as the "wearing out" of the soil. When the reclamation act was passed, it was known that wherever irrigation was being practiced on any considerable scale, there was a tendency to swamp some of the lower land, also for the earthy salts, known as "alkali," to develop on or near the surface, ruining the cultivated field. In a well irrigated country, as for example, near Salt Lake City, Utah, it was estimated that from 15 to 20 per cent of the land, productive in the earlier years of irrigation would ultimately thus be injured. It was assumed, however, that on government projects, with the greater skill used in the works and in their operation, and better economy of water, these land losses would be greatly reduced.

The investigations by Carl Scofield, which were described in a previous article, are casting a light on this somewhat obscure subject of soil deterioration. Its effects are all too plainly visible in decreased productivity, as illustrated by the accompanying figure (Fig. 3) which shows the reduced yields of alfalfa hay, seed, and cotton. Here is a case where economy of water has been carried to an excess. Apparently, a far larger amount must be put upon the land to wash out the alkali which is accumulating. Similar conditions have been noted in Salt River Valley where lands which have been producing heavily in cotton were said to be "worn out." As a matter of fact, analysis showed

FIG. 1.—PROPORTION OF LAND OWNERS HOLDING ONE OR MORE GOVERNMENT-RECLAIMED FARMS, AND THEIR SUCCESS OR FAILURE

tically valueless. The remaining 27 per cent, many in the hands of non-resident owners, must be considered as unsuccessful at present. Many of the latter can be converted into successes, however, by proper administrative control, except in cases where the lands have already been ruined by bad management.

Under existing conditions, it is somewhat remarkable that so many have succeeded on the land, but there has been a vast amount of unnecessary hardship, suffering and loss, because as previously stated there has been no way to prevent the unqualified homestead entryman or woman or purchaser of these lands from deceiving themselves or being deceived regarding the difficulty of pioneering.

The accompanying diagram (Fig. 1) illustrates the proportion of successful and unsuccessful landowners on the reclamation projects. The greater number of these, 54 per cent, include persons who have observed the spirit of the reclamation act, who have confined their efforts to a single farm unit and have lived upon this and cultivated it.

A considerable number of the land owners have not been satisfied with a single farm, which in the opinion of the Secretary of the Interior was adequate for the support of a family, but have acquired two farms, or

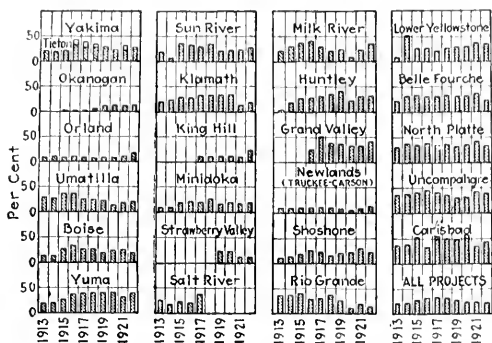

FIG. 2—FINANCING—PERCENTAGE OF TENANTS 1913 TO 1922 ON U. S. RECLAMATION PROJECTS

that the application of two acre-feet of water per acre, as has been the custom, tended to leave the salts in the soil. To wash it out and restore conditions of tilth would require at least two acre-feet additional with a corresponding doubling of the cost of the water.

Transportation and Marketing—When the lands on the government reclamation projects were first irrigated, there was usually a considerable demand in the immediate neighborhood for the alfalfa and other crops which were then produced. This was because contractors were still working in the vicinity and many persons were erecting buildings in the new towns and utilizing considerable numbers of men and of animals. The amounts received for the crops produced was notably large, being determined by the price in the outside markets, plus the cost of freight. In a few years, however, the conditions were completely changed.

With the development of larger areas of irrigated lands there were produced greater quantities of food and forage than could be disposed of locally, especially after the contractors and builders had left the vicinity. Then the prices suddenly dropped to those in outside markets, minus the cost of freight to these outside markets.

Every acre of the irrigated land has been or should be put into alfalfa or some other clover at one time or another in order to aid in the development of nitrifying organisms in the soil. To picture the desirable condition it is as though a crop of alfalfa was spread down and then rolled up as the fields after a few years are plowed and put into cultivated crops. Many of the land owners, however, having once put their land into alfalfa, prefer to let this crop remain and are unable or unwilling to practice the systematic crop rotation necessary to maintain or increase the soil fertility. They must find a market for the alfalfa hay in the immediate vicinity or else ship it to distant points. The local market is quickly glutted and there has resulted the economically unstable condition where hay is being shipped off the project and butter and pork shipped in. It is or should be obvious that no group of farmers can be permanently prosperous where this condition exists.

The experts in marketing of the U. S. Department of Agriculture have studied the situation and have given excellent advice, all which may be summed up in the recommendation that the heavy products such

as hay and grain be manufactured on the farm or in the immediate vicinity into the more condensed form such as beef, pork, mutton, poultry, eggs and butter fat, retaining the fertility on the farms and shipping out only these condensed products—in other words, following the mottoes of "Feed the family from the farm and feed it first"; also "Feed all you raise and raise all you feed." Like other simple and obvious rules, this is not always easily followed, the advice has not been particularly palatable to men who have been accustomed to the one crop method. The location of the reclamation projects, however, remote as they are from large marketing centers, requires for ultimate continuous prosperity that some such method be adopted.

Have Settlers Had Adequate Help?—The question is frequently asked as to whether the government, state and national, has done all that it can or should to facilitate the creation of homes on the reclaimed lands. Many people assert that too much has been done and that communities as a whole would now be far better off if less of what might be called "paternalism" had been displayed. On the other hand, there is a steadily increasing demand that more and more aid be given, not merely in the way of sound agricultural and economic advice by county agents and experts of the state and national Department of Agriculture, but by going further, particularly in the way of credit facilities.

There is no doubt that the pioneer farmer must be afforded certain credit facilities. At the same time experience has shown that unfortunate conditions have arisen from the obtaining of too easy credit, notably during the time of inflated prices following the world war. As a result of these, many of the land owners on reclamation projects invested in other lands, in oil stock or in equipment such as automobiles which they really did not need. In short, taking the projects as a whole, there has been perhaps not too much credit but frequently an unwise use of the credit which was available. This is to be expected because many of the settlers upon the reclaimed lands were people who, through lack of thrift or "bad luck," have been induced to leave their former homes and who, with characteristic optimism, plunged into new enterprises to the full extent to which they could secure credit.

No help has been given directly by federal agencies in this matter of financing or credit other than that above described which arose indirectly out of the fact that the land owner was able to obtain possession of a tract on which the government had expended several thousand dollars and on which he was not paying any interest. This gave him certain opportunities for bor-

FIG. 3—PRODUCTION PER ACRE PER YEAR ON YUMA PROJECT

Showing the effect of accumulation of alkaline salts in the soil in reducing the yield per acre.

rowing other sums, on what is sometimes considered a second mortgage at high rates of interest.

In the matter of aid and advice, however, the national government, in co-operation with state authorities, has been liberal, responding to every inquiry and sending out printed matter not only in the form of pamphlets but also in a series of short statements used by the local press. Special appropriations have been made for investigations and for experimental farms on government projects. In round numbers, over a million dollars has thus been expended producing results of great value such, for example, as those which led to the planting of the long staple Egyptian cotton in the Salt River Valley, from which millions of dollars in profits have been received.

This work of experimentation and demonstration is necessarily slow; it requires great patience and persistence because the building up of better methods of agriculture or the spread of correct information regarding crop rotation and marketing necessitates man-to-man contact continued through months or years. The same is true of dairying, which has been notably successful on several of the projects, for example, on the Newlands in Nevada. This success is due to the quiet persistence of one or two men who have slowly overcome prejudice and various obstacles of human origin, finally getting the farmers to realize the true value of a good system of dairying.

The problem everywhere is to induce the farmer on the newly irrigated land to forget much of his former experience and to adopt the methods which agricultural experts and experienced farmers in the vicinity have found to be most successful. The inertia is great, and where a man has been accustomed to raising wheat only or alfalfa only and has an equipment for this purpose, finishing his entire work for the year in a relatively few weeks, he is unwilling to go into dairying, for instance, which requires daily attention throughout the entire year.

From what has been given in the preceding paragraphs, it must not be inferred that reclamation as a whole has not been a success. Rather, the contrary. Human interest is attracted, not by the rather prosaic statements of the successful enterprise, due to patient plodding and thrift, but by the unusual or extraordinary conditions of failure and the reasons for these. It is easier to draw a lesson from such failures than it is from the daily routine of a uniformly successful process.

The real measure of success as regards the reclamation work is measured, as before stated, by the predominance in numbers of prosperous and contented homes. The more convenient measuring stick is, however, that of the dollars which have come back from the investment made. While it is true that as yet not much more than 10 per cent of the original investment in the reclamation works has been returned to the federal treasury for use over again, yet this is not an indication of the breakdown of the theory but rather of the attitude of Congress in extending the time of payment. This was done under the belief that even if the money was not repaid at an early date the benefits through the development of homes and communities more than repaid the losses in interest on the investment.

Summing up the whole situation, it may be said, as in the beginning, that the law has been a success. It

can be made a greater success in the future if the law makers and the executive officers will be able to apply the lessons taught and will have clearly in mind the object to be attained, namely, the creation of rural homes. Incidentally, it should be emphasized that when the reclamation act was passed, it was assumed that the greatest possible development of homes would be on the vacant public lands of the west. The studies made by the Reclamation Service in other parts of the United States, however, and published in 1919 (*Development of Unused Lands*, 66th Congress, 1st Session, House of Representatives, Document No. 262. Oct. 10, 1919. 184 pages) show that under present conditions the largest and best development of homes can probably be made on the unused lands of the South and East. The cost is far less than in the West because of the inflated land prices which have resulted in the West from over-exploitation of irrigable lands. The hope, therefore, of many public men is that the reclamation policy may be made truly national as contrasted with its present local or sectional character, and that under a revised law, based upon the experience of the past twenty years, larger and even more effective activities may be conducted throughout the United States wherever suitable unused lands exist as rapidly as needed for the creation of the small self-supporting farm homes, the backbone of our national and business institutions.

[Further articles in the series will deal with past experiences and problems of reclamation and with future development. In next week's article George F. Kreutzer will discuss land settlement problems—EDITOR.]

Reorganizing Austrian Railways

A LAW has recently been passed providing for the reorganization of the Austrian State Railways, in order to place them on a satisfactory economic basis, and for the creation of a corporation in Vienna for the purpose of conducting the operations of the federal railroads. This corporation must administer the entire property of the railways and act as a trustee for the government. The government is to furnish a capital of 200 milliard crowns, and is to cover any deficits.

An executive committee of five members will be held responsible to a commission of fourteen directors for actual operations. Eleven members of this commission are to be business men or experts in handling transportation problems, and are to be appointed by the railway government for a term of three years. Three members are to be chosen by the railway employees. The executive committee to be appointed by the commission and may be recalled by consent or order of the government. The chairman of the committee will have the title of general manager; each other member that of manager.

In addition to managing operations the executive committee must pass on all reorganization questions, formulate operating policies and plans, appoint and manage the personnel, and submit a financial balance sheet monthly and annually. It may raise short term interior loans of low denominations. The commission of directors is charged with general supervision and with safeguarding the public interests.

The government reserves the right to give or withhold approval of tariff changes and large or long-term loans and will supervise social and safety measures and regulate construction and maintenance.

Birdseye Party Completes Survey of Grand Canyon

U. S. Geological Survey Men Successfully Map Last Stretch of Treacherous Colorado—Dam Sites Investigated—Barely Escape Flood Waters—Thrilling Events Recounted

THE LAST stretch of the canyon of the Colorado that had not been surveyed in detail for accurate mapping, has at last been traversed by a party in charge of Col. C. H. Birdseye, chief topographic engineer of the U. S. Geological Survey, in a trip ended last month through 300 miles of the roughest waters and most treacherous section of the Colorado. The trip began at Lees Ferry, Ariz., and ended at Needles, Calif., and took approximately three months to complete. The chief purpose of the trip was to make an accurate survey of the canyon and to locate sites at which dams could be built to utilize the wasting waters for flood prevention, power development and irrigation. The trip was made in four principal boats, supplemented by a canoe, which however was later lost. These boats carried not only supplies and surveying and geologic instruments, but, except where portages were made, the members of the parties themselves.

The party consisted of well-seasoned experienced men, comprising, besides Col. Birdseye, E. C. LaRue, who has made a study of utilizing the Colorado River waters; R. C. Moore, state geologist of Kansas; R. W. Burchard, topographic engineer of the Survey, who had already surveyed the lower stretches of the river; Emery C. Kolb, of Grand Canyon, who with his brother made a boat trip from Green River, Wyo., through the Grand Canyon to the Gulf of California in 1911; Lewis R. Freeman, of Pasadena, Calif., explorer, writer and boatman; Leigh Lint, of Weiser, Idaho, and H. E. Blake, Jr., of Monticello, Utah. These two latter are young men of two years' experience in boating the rapids of the Colorado. Frank B. Dodge, of Honolulu, was another member of the party, being a skilful boatman, expert swimmer, and general utility man capable of filling any position from instrument man to cook. Frank Word, of Los Angeles, was the cook. About 90 miles below Lees Ferry, the party was joined by Herman Stabler, hydraulic engineer of the Geological Survey, and at Supai Creek by Felix Koms, who replaced Frank Word as cook. Following is an abstract of Col. Birdseye's report of the trip:

The party left Flagstaff, Ariz., July 18 for Lees Ferry, 140 miles away. One boat and all provisions and instruments for the trip were carried on two motor trucks. This 140-mile stretch of road included some perilous going over what is called the "dugway," a narrow road blasted out of the cliff, which at places rises about 300 ft. above the river. The job of steering a heavy truck laden with an 18-ft. boat around the perilous turns in this road lent considerable interest to the beginning of the trip. The other boats used were the property of the California Edison Co., and had been in use in 1921 in Cataract Canyon, above Lees Ferry. The party spent the rest of July making new topographic surveys around Lees Ferry and getting ready for the boat trip.

River Trip Begins—Leaving Lees Ferry Aug. 1 the party camped the first night $7\frac{1}{2}$ miles below that place, where the radio set was tried out and in spite of adverse prophecies that a radio would be unable to get anything in the depths of the canyon, the Los Angeles broadcasting station was picked up. The canyon at that point is narrow and nearly 1,000 ft. deep. The next morning Badger Creek rapids were run. These rapids have a fall of 13 ft. in about 100 yd. and to the party just then beginning its trip,

they looked wild, but later experiences with rough water made them appear slight upon recollection. Camp the second night was made about 11 miles below Lees Ferry, where the party learned by radio of President Harding's death about three-quarters of an hour after it occurred.

On Aug. 3 the party portaged boats and equipment past Soap Creek rapids, carrying and skidding the upper part of the rapids, but successfully running the lower rapids. These rapids have never been safely run by any party. It was man-killing work to portage the heavy wooden boats here. Perhaps we might have got through safely without portage, as we ran worse rapids later, but it did not seem wise to take the chance so early in the trip.

The first rapids which all the members of the party ran were encountered on Aug. 4—rapids which the party called "Sheer-Wall Rapids," due to the fact that there was no foothold for portage. Rapids were run with the boat stern first and with all occupants wearing life jackets of cork, with kapok collars. Members of the party lay face down in the boats, clinging hard to the life lines stretched across the deck. The waves seemed mountainous and to some of us our first ride of this kind was a genuine thriller, but we afterward became so used to riding rough water that we vied with one another to make the plunge with a lighted pipe or cigarette without losing the light.

On Aug. 5 the boat passed a boulder measuring 40 x 80 ft., rising 30 ft. above the water. This boulder, standing almost in the middle of the river, has been mentioned by nearly all who have written accounts of canyon trips. Seven rapids were run on Aug. 6. On the evening of that day, the party camped near some good springs on the right banks of the river, a place which was called Spring Cave rapids. In an attempt to "line" the canvas canoe around Spring Cave rapids, it was lost, the only mishap of the kind during the trip.

Dam Site Surveyed—After several other rapids had been run, on Aug. 8 the boat passed Vasey's Paradise, 31 miles below Lees Ferry. The party filled canteens from a large stream of clear cold water gushing from the cliff about 70 ft. above the river. Surveys of a possible dam site were made at this point, and camp was pitched on the limestone ledges at the head of another rapids where radio messages were received from Los Angeles broadcasting station.

On Aug. 9 about 41 miles below Lees Ferry, the party passed by some fine arches in the limestone wall of the so-called Marble Canyon. Here the walls, which rise about 2,000 ft. above the river, have been sculptured into remarkable forms by erosion and by the fall of great masses of rock. Advantage was taken of a severe rainstorm for all members of the party to get the first real bath they had had since leaving Lees Ferry.

On Aug. 10 the party remained idle as a tribute to the memory of the dead President.

Aug. 11 the boatmen ran the little fleet through Boulder rapids, below which quieter water was found, and in this stretch 46 miles below Lees Ferry the party passed three large caves, which they called the Triple Alcoves. On Aug. 12 Nankoweap Creek was reached and more clear water for drinking purposes was found. As the Colorado is decidedly muddy and carries 10 per cent of sand and other suspended matter, clear water for drinking was a luxury. In camp that night at the mouth of Kwagunt Creek, daily news items and baseball scores, as well as concerts, broadcasted from Los Angeles were picked up on the radio. The party ran Kwagunt rapids the next day, reaching the mouth of the Little Colorado River, which was in flood and poured into the main stream a great volume of yellow water, dirtier than that of the Colorado.

Marble Canyon Left—The mouth of the Little Colorado marks the end of what is called Marble Canyon and the

beginning of what is called the Grand Canyon, but the whole stretch of the river through the plateau from a point a few miles below Lees Ferry downstream might well be called the Grand Canyon. The distinction had been made, so the party began to reckon its progress down the canyon in miles from the mouth of the Little Colorado. That night the river rose 3 ft. and the party had to arouse itself and hustle to pull up the boats. By mid-August the party was thus working its way downstream through rapids after rapids, each day bringing its touch of adventure or experience. The engineers had become accustomed to rough water and wanted to ride the boats through the most threatening cataracts, and the better judgment of the boatmen had to be expressed forcibly to induce them to climb around on the rocky and narrow shore. At some places, however, portage was impossible, so the whole party had to shoot through on the boats together and take chances alike.

At the foot of Hance trail a pack train was expected, but as the party was more than a week ahead of its schedule, the train of course was not there, so three of the party climbed the canyon to its south rim at Grand View 5,000 ft. above and 15 miles away, reaching the rim at midnight and spending the night with a forest ranger, who drove them next day to El Tovar. The following day all returned to the canyon with a pack train bringing supplies and mail.

Re-equipped, the party passed Hance rapids, which is one of the worst on the river, having a fall of 28 ft. in a few hundred yards and being full of rocks over which the river surges in great waves. However, all boats made the trip safely, though all took water. Not far below Hance rapids, the party entered the upper Granite Gorge, a point where difficulty was experienced in securing a foothold for instrument and rod stations. However, the survey line was carried through without a break. The walls here are only about 125 ft. apart at the water's edge, and at some places the surveyors had to cling perilously to small projections just above the swirling water.

Sockdologer Rapids Run—The dreaded Sockdologer rapids, 17 miles below the Little Colorado, were reached Aug. 21. The height of the fall here has been exaggerated greatly, amounting to only 19 ft., but most of it occurs in the first hundred yards. Waves measured 20 ft. from

trough to crest. All members of the party had to take to the boats. The next morning the boats plunged into Grapevine rapids, which have a fall of 17 ft. in a few hundred yards and are full of rocks. At this place, as at most places in the Upper Granite Gorge, it is impossible to climb around the rapids, so that the whole party shot through in boats. Between all these perilous plunges down dangerous cataracts, the surveyors carried along their work. A continuous line was run through the canyon and detailed surveys were made of possible dam sites at several places.

At the mouth of Bright Angel creek, the party passed under the Geological Survey's gaging cable and the suspension bridge, a frail looking structure, affording the only good crossing to the north rim of the canyon in the whole stretch of the river through the plateau. At this point most of the members of the party climbed out of the canyon to return on Aug. 28 to find a Fox News operator prepared to take moving pictures of the party running the rapids. The operator rode in one of the boats with his camera and took a number of pictures of the party, both in camp and in the boats as they plunged through the rapids. The boats shot through rapids in quick succession at Pipe Creek, Horn Creek, Salt Creek and Monument Creek. The latter, shown on the Geological Survey's map as Granite Falls, has a drop of 17 ft. and is piled with great rocks that throw the water into high waves. Here the boats shipped considerable water.

Party Receives Visitors—On the evening of Aug. 29 the party camped at the mouth of Hermit Creek, where a good flow of drinking water was found. Here it was joined by Col. W. W. Crosby, superintendent of Grand Canyon National Park, and a large party that had been made up to see the boats run Hermit Creek rapids. So many visitors caused the cook to threaten to leave, so arrangements were made to replace him. Hermit Creek rapids proved to be extremely rough, the boats tossing about like corks on the huge waves, many of which broke over the boats. The fall here is about 15 ft. During the night of Aug. 30 a terrific thunderstorm wet the whole party in spite of rubber sleeping bags and other means of protection. As the rain bordered on a cloudburst, the next morning was devoted mainly to getting things dry.

U. S. GEOLOGICAL SURVEY PARTY WHO HAVE COMPLETED PRELIMINARY MAPPING IN GRAND CANYON
Left to Right—Leigh Lint, H. E. Blake, Jr., Frank Word, Col. C. H. Birdsseye, R. C. Moore, R. W. Burchardt,
E. C. La Rue, Lewis R. Freeman and Emery C. Kolb.

Crystal Creek rapids were next run, and on Sept. 2 the party reached Bass trail, where the pack train had brought a large stock of supplies, which were loaded into the boats taxing their capacity, yet consisting of no more than was necessary to carry the party to Diamond Creek, more than 100 miles below. The boats ran Bass Canyon rapids, passing under the upper Bass Ferry cable, upon which a man in a car can propel himself across the river with a windlass. The cable is about 50 ft. above the water and 300 ft. long. The lower Bass cable crossing is a few miles below, carries a smaller car, and appears to be not so secure. At this point detailed surveys were made for a promising dam site. Several miles below the lower cable crossing, the party encountered Royal Arch Creek, whose canyon contains a clear, cold stream and beautiful falls, pools, and fern dells. No account of any boat trip down the canyon contained any mention of this spot, but a Geological Survey party had evidently camped there, the remains of a camp fire being found and on the rocks nearby were carved Geologic Survey inscriptions dated May, 1905, and June, 1907.

Two Dangerous Rapids Encountered—After shooting these rapids, the most threatening having a fall of 15 ft., the party, after a day's run of 9 miles, camped on Sept. 6 at Specter Chasm. About a mile and a half below this place, the boats took an 8-ft. rapids, in which the party seemed to be in greater danger than at any other point. The channel was shaped like an "S," and the swift current tends to drive a boat against a large mass of rock lying halfway down the rapids. Two of the boats missed the rocks narrowly, one of them coming so close to it that Burcharth touched it with his hand. One boat actually struck the rock, but so lightly that no damage was done.

On the morning of Sept. 8 the party reached a cataract that no preceding party had yet run. It had a fall of 15 ft. in a few hundred yards, and is full of rocks and bad holes. The first boat through grazed the rock and lost an oar, but the oar was recovered and the boat pulled through. After getting through, however, its operator signaled the others to take the midchannel. The next boat struck near the lower end of the rapids a rock on which it seemed to hang for a moment. On pulling out of the rapids, it was found they both had a bad smash in the stern, and that the stern hatch was leaking. This mishap consumed an hour in repairs with cotton waste, white lead, canvas, and copper sheeting. The other boats had no mishaps.

At the mouth of Tapeats Creek, which was reached on the afternoon of Sept. 8, the party found a cold stream of clear water and decided to spend the next day, which was Sunday, in camp. LaRue discovered that this creek had the greatest flow of any theretofore encountered, except the Little Colorado, its flow measuring 96 sec.-ft. About two miles up the creek the party found that half the flow came from a series of cascades from the west, and on tracing this side stream farther up found it gushed from a large cavity in the cliff. In the trip up the creek several Indian ruins and some arrow heads were found.

The next day the boats plunged through Tapeats Creek rapids and along rapids nearly a mile farther down, below which Deer Creek comes in from the right through a cleft in the wall of the canyon in a waterfall about 75 ft. high. A mile farther downstream some old Indian ruins were passed.

The party reached Fishtail Canyon at noon Sept. 10 and saw the eclipse of the sun, which there was 75 per cent total. The canyon looked particularly gloomy and desolate in the dim light.

Below Kanab Creek, the party found shelter from a long and violent thunderstorm in a cave at the head of a dangerous rapid. Here, after the storm, Kolb ran the rapids first and was drawn into a swirl in a big hole, where his boat turned upside down and he disappeared. Dodge at once plunged into the torrent and swam to the boat, catching it at the foot of the rapids. It had come up on the side of the river away from the party, and for several minutes it looked as if Kolb were gone, but Dodge found him under

the cockpit, almost unharmed, though he did cough up some water.

Party Again Provisioned—Nearly at mid-September the party reached the mouth of Havasu Creek, 95 miles below the Little Colorado, and about 155 miles below Lees Ferry. Here Roger Birdseye and Charles Fisk, the provisioners of the party, were waiting with nineteen Supai Indians as packers, bringing supplies to last until the boats reached Diamond Creek, nearly 70 miles below. The Indians would not pack more than 40 lb. each and were so afraid of being overloaded that every man's pack was weighed at the Indian agency. Many amusing incidents were reported, such as the exchange of a package of oatmeal for a can of beans, in order to reduce the weight of the pack by a quarter of a pound. Although the reservation is less than 10 miles from the river, none of the Indians had ever made the trip down the narrow, steep gorge. Below Havasu Creek the boats were run through rapids safely and the journey was enlivened by thunderstorms and small adventures.

Camp was made on Sept. 18 on a small sandbar below the falls. At half past six in the evening the river began to rise and at 8 o'clock the boats, which were moored in a small cove, were pounding so badly it became necessary to find a safer place for them. Kolb and Lint therefore pushed off downstream in one of the boats in the darkness, with lantern and flashlight, and in about an hour returned overland to report that a small sand beach with a low shelving shore of limestone, up which the boats might be pulled, lay not far below, and that they had left the boat there.

Flood Threatens Disaster—No one expected a rise of more than 5 or 6 ft., but the river had already risen 3 ft. and the boats could not be held longer. There was space at this place for pulling one boat well above the water, so the cook boat was dragged up the side of the cliff by means of block and tackle. Kolb, Freeman, Lint, and Blake ran the other two boats downstream to the place selected, though not without difficulty. Freeman climbed back along the shore, but the other three remained for a sleepless night, for the water rose rapidly, and they were kept busy pulling one boat or another out of the water to a higher place on the bank.

At 11 o'clock the cook boat was afloat and had to be pulled up higher, though the job was not easy, for the waves lashed the rocks so vigorously that secure footing could not be found below the boat. Felix, the cook, went to bed 10 ft. above the water but was flooded out at midnight, and the others had to rescue his bed and clothes. During the night the beds with the cook's outfit had to be moved three times. I went to bed at 2:30 a.m. on a flat rock 20 ft. above low water but two hours later was awakened by the spray lashing the rock. At daylight all hands went downstream to see the other three boats and found them pounding in the waves but all safe.

At 8 o'clock on the morning of Sept. 19 the river had risen 16 ft. and it continued to rise all day, reaching a peak of 21 ft. about 6 p.m. The party spent most of the next day rather enjoyably in washing themselves and their clothing in the warm springs at this place, for the night had been chilly. Exercise was found in pursuit of a large rattlesnake, which was killed.

In the flood the rapids, which had been a short, almost sheer fall of 10 ft. at the crest, became a long sweeping "v" of swift water, and the waves below the crest for a quarter of a mile were running 20 ft. high and throwing spray that much higher. Immense quantities of driftwood, including many large logs, were carried downstream, and some of them were thrown completely out of the water. Measured in volume the rise was estimated to be 100,000 sec.-ft. Evidently the rainstorms that had drenched the party from Sept. 13 to Sept. 16 were accompanied by worse storms farther up the canyon.

The river subsided slowly during the two following days, and on Sept. 22, with the river about 7 ft. above the old low water stage, the party resumed its journey.

Party Reports by Telegram—On Oct. 2 after running many small rapids, the party reached Diamond Creek, 164 miles below the Little Colorado, and 225 miles below the starting point. The party was reprovisioned and from that point telegrams were sent to Washington and elsewhere, reporting the safe arrival of the party and putting at rest rumors that the party might have suffered disaster because of the finding of a strange boat below. Here also the boats were overhauled, reports prepared, equipment examined, and radio outfit repaired and set up. Among the things received by radio was the announcement that the party itself had arrived safely at Diamond Creek.

The voyage was resumed Oct. 7, the boats plunging into Diamond Creek rapids. During that day Burchard fell on the rocks, fracturing a rib, but insisted on continuing his survey. With the exception of the first day's work below Lees Ferry he had made the entire survey and wanted to carry the line down to connect with his old work, just above the mouth of the Grand Canyon. He is therefore responsible for the entire survey through Marble, Boulder, Grand, and Black Canyons, from a point 7 miles below Lees Ferry to the Bull's Head reservoir site, about 40 miles above Needles. Though his rib was painful, bandages made it possible for him to continue the work.

Boat Thrown Into Air—Separation rapids were the next dangerous ones met. At the mouth of a deep canyon that comes in from the right, they fall nearly 20 ft., looking dangerous, and sheer walls leave no chance to pass around them. It is here that three members of the first Powell expedition are supposed to have left the canyon in discouragement, being soon afterwards killed by Indians. Kolb, Blake, and Lint ran their boats safely, but the deck loads made the boats top-heavy, causing them to dance about in the torrent like corks. Freeman ran last, with LaRue and Moore clinging to the hatches. The huge waves tossed the boat into the air, and when it came down, bottom side up, they were thrown out between the boat and the rocks, LaRue narrowly escaping being crushed. Freeman had divined clear of the boat and had come up a few yards from it, where he caught a rope. Blake and Dodge pushed out in their boat to render assistance. Dodge grasped the painter and helped to haul LaRue aboard, Freeman and Moore holding hard to the upturned boat, which was towed to quieter water and righted. All lost such loose articles as hats, pipes, and glasses, and Freeman lost both oars, which, however, were afterward recovered.

The accident afforded a good test of the serviceability of the watertight boxes, one of which, containing cameras, was strapped in the open cockpit of the overturned boat. After a half hour's submersion the cameras and films were found bone-dry. In camp that night, the radio set gave messages from Los Angeles, Salt Lake City, and for the first time from Colorado Springs.

Mattowitkeki rapids, which lie below Mattowitkeki Canyon, were next run. The fall here is 17 ft. in about a hundred yards, and the channel is dotted with rocks. One of Powell's boats broke loose while it was being lined around, and one man was thrown out but rescued. These rapids—the last bad fall on the river—are considered the worst in the canyon except Lava Falls. The boats were lined through by using long lines held by men at several points along the cliff. The job of handling these 900-lb. boats and portaging equipment was not easy.

On Oct. 13 Burchard brought his line to the monument marking the end of his work in 1920, at Last Chance rapids, 252 miles below Lees Ferry, and checked his elevations, finding only a slight error. On Oct. 15 the voyage downstream was resumed, and the party reached Needles, 450 miles from Lees Ferry, on Oct. 19.

To the able leadership of Colonel Birdseye is attributed a large measure of the success of the trip. The persistence of "the indefatigable Burchard" was a matter of comment among his companions as was the skill and good judgment of Emery Kolb in piloting the boats through the rushing waters of the canyon.

Siltation of Austin and Lake Worth Reservoirs in Texas

By JOHN B. HAWLEY
Consulting Engineer, Fort Worth, Texas

Remarks before Texas Section, Am. Soc. C. E., Oct. 5, 1923.

DEAN T. U. TAYLOR'S excellent paper on the silting up of the Austin reservoir in *Engineering News-Record* for Sept. 6, p. 380, while accurately setting forth the facts, is quite likely to be too greatly generalized by the casual reader, even to the extent of concluding that reservoir construction in Texas is a futile undertaking.

The situation at the Austin dam is quite unusual, especially in respect of the great drainage area, 37,000 sq. mi., for an original impounding capacity of 16,800,000,000 gal., or 51,000 acre-ft. Dean Taylor shows that 84 per cent of the capacity of Lake Austin was filled with silt from 1913 to 1922 (reducing a capacity of 33,745 acre-ft. to 5,156 acre-ft.). This makes Lake Austin look quite like a mere "sand-trap" for the 37,000-sq.-mi. drainage area.

Now Lake Worth, on the West Fork of the Trinity River, six miles west of Fort Worth, has been in service slightly more than nine years, 1914 to 1923. Its drainage area is about 1,600 sq. mi., the areal geology of which is quite similar to that of the Colorado River above Austin. The gross capacity of Lake Worth, at spillway level, is, or was, about 14,000,000,000 gal. or 42,000 acre-ft.

In the Austin case 37,000 sq. mi. fed 33,000 acre-ft. capacity, or 1.12 sq. mi. for each acre-foot. In the Fort Worth case 1,600 sq. mi. fed 42,000 acre-ft. capacity, or 0.038 sq. mi. for each acre-foot. Axially, Lake Worth is about twelve miles long and has an average width of a half mile.

Some months ago, when the water level of Lake Worth was 4 ft. below the spillway, John F. Norris, Simon W. Freese and the writer carefully examined the shores of Lake Worth, digging through the reddish silt into the original black loam. The line of contact was clearly defined. Near the dam we found an average of $\frac{3}{4}$ in. of silt; $\frac{3}{4}$ mi. above the dam, $1\frac{1}{2}$ in. of silt; and 7 mi. above the dam $\frac{3}{4}$ in. of silt. The last observation was made about $\frac{1}{2}$ mi. above the "Nine Mile Bridge," just below the "narrows" between the "upper" and "lower" lakes. Sometime later the writer made some examinations near the upper end of "upper lake," and found 2 to 3 ft. of silt at the low-water mark.

Lake Worth Siltation—The data are inadequate to estimate siltation for the nine years, as the depths of the lake will show much greater silt deposit than the shallows, but the contrast between them and Dean Taylor's figures for Lake Austin is striking. However, if Lake Austin, with approximately the same capacity as Lake Worth, was 84 per cent filled by silt from 37,000 sq. mi. of drainage area in nine years, then perhaps Lake Worth, with but $\frac{1}{2}$ per cent of that drainage area, might go 207 years before accumulating silt to 84 per cent of its original capacity. Again, assuming that the 4,200-acre water surface area of Lake Worth has been silted an average of 1 ft. during the nine years (and this assumption is deemed excessive) the silt volume would be but 10 per cent of the original capacity, as against 84 per cent in the case of Lake Austin.

The State Board of Water Engineers and the Engineers of Water Resources (for Texas) of the United States Geological Survey recently decided to make soundings on traverse lines to be established on Lake Worth, and to continue observations on its siltation through a long period of years. Data secured by these observations will be eagerly awaited by the profession.

The many impounding and storage reservoirs on Texas streams, and streams in every other state, many of them in useful service for decades, should be ample evidence to engineers, and to communities contemplating the conservation of surface waters, that the siltation troubles experienced at Lake Austin are substantially unique, being probably the most unusual in the history of engineering.

Engineering Literature

A MONTHLY REVIEW OF BOOKS AND A LISTING OF NEW PUBLICATIONS

An Engineer on City Charters

THE BEST CITY CHARTER.—By Robert J. Harding, M. Am. Soc. C. E. With an introduction by George Chandler Whipple, Professor of Sanitary Engineering, Harvard University. San Antonio, Texas: The San Antonio Water Co. Paper; 68x9 in.; pp. 89.

As engineer and administrative officer for cities in the North and as chief engineer, manager and vice-president of a water company in the Southwest, Mr. Harding has had both experience in city administration and much contact with city governments. In addition he has collected and studied city charters of different types. The result of all this, plus much thought on the subject, is this essay on *The Best City Charter*.

Briefly, the author believes that a city charter should take the doctrine of representative government as its basic principle and the Constitution of the United States as its model. While seeing some advantages in the commission and commission manager as contrasted with earlier types of city charters, Mr. Harding is against both of the newer forms. These he considers unrepresentative and, as regards their common accompaniments—the initiative, referendum and recall—ultra democratic. But, strong as he is for representative government, he proposes to deprive the voters of the power to choose one-third of the city council by having the choice made by the mayor—from citizens especially qualified for the purpose who would at the same time raise the level of a body of ward representatives. So far as we know, such a limitation of representative government has never before been proposed.

Impressed with the fact that the commission plan is an abandonment of the separation-of-function-and-power idea of the American Constitution but largely if not wholly ignoring the development, a few decades back, of the federal type of charter, as at Brooklyn and Cleveland, and in the first model charter of the National Municipal League, Mr. Harding proposes a decidedly mixed type of charter with (1) a mayor of limited executive power; (2) a council with practically none but legislative functions; (3) numerous administrative boards on the theory that by this means the interest and knowledge of representative citizens will be put at the disposal of the city; (4) department executives and employees, apparently chosen in part by their immediate heads and in part by civil service commissions, but not as regards men to fill technical positions. Except for the health commission, these administrative boards seem to be limited in power to (1) the choice of an executive head of the department; (2) carrying out policies established by the city council and expending money provided by the budget; (3) recommending measures to the council for approval.

An engineering board would appoint a city engineer, initiate street widening and extension projects and have some control over utilities that use the streets, but there would be a board of public works to initiate public improvements and to construct and operate various public works, under the "direction of a man," chosen by the

board, "preferably a municipal engineer with wide construction experience." In cities of less than 50,000 these two boards might be combined. The health board would have charge of plumbing and of city scavenging. There would be no curb on its expenditures so long as they were for public health.

The mayor is held to be the chief executive but from Mr. Harding's outline he seems to be that only in so far as appointment of board members is concerned. The mayor is also the "prime mover" as to policies while the council acts "as a buffer between the initiative [initiator?] and the people." Mr. Harding differentiates between the administrative and the executive functions of city officials, and Professor Whipple, in his introduction, enlarges considerably upon Mr. Harding's few lines on this subject. Both have in mind (1) legislation; (2) administration, to work out the details of legislative policies; and (3) execution of those policies as thus detailed, but Mr. Harding's scheme does not follow this division in a clean-cut way.

Rightly or wrongly the essay gives the impression that the author has largely ignored much if not most of what others have written on democratic institutions, representative government and city charters. Other proposals to improve city government, especially by the commission and commission-manager plans, adopted in the last twenty years by some six hundred cities and given up as yet by very few, the author characterizes as innovations, prompted by a desire to change. Notwithstanding the foregoing criticisms Mr. Harding's essay is well worth reading, especially by engineers, but those not already familiar with the two-hundred commission-managers charters now in use and with the theory and practice of charter making will do well to refer to Crane's "Digest of City Charters," and to read one or more of the many recent books on government—federal, state and municipal—and also Mill on "Representative Government."

The Engineer Who Makes a Speech

REVIEWED BY P. B. McDONALD

Professor of English, College of Engineering, New York University
PLATFORM SPEAKING.—By G. Rowland Collins, of New York University. New York: Harper and Bros. Cloth; pp. 341; \$2.25.

For the engineer who has to make a speech here is a useful book of instructions designed especially for professional and business men. All varieties of formal talks, from the sales argument to the after-dinner speech, are discussed in a practical and helpful manner. The technicalities of voice and action are minimized, and stress is laid upon preparation rather than upon presentation in the old-fashioned elocutionary style. Analyses of purpose, subject matter, and audience are particularly well treated. While avoiding the old elocutionary etiquette, the author has not gone to the other extreme and descended to "pep" phrases and inspirational lingo. The methods of effective persuasion and argumentation are made plain.

From Serbian Cattle Herder to Scientist

FROM IMMIGRANT TO INVENTOR.—By Michael Pupin, Professor of Electro-Mechanics, Columbia University. New York: Charles Scribner's Sons. Cloth; 6x9 in.; pp. 396, 25 halftones. \$4.

Seldom does an autobiography have such breadth and height of interest as does Prof. Pupin's story of how a boy cattle herder in Serbia became an American scientist of world-wide fame. Many other foreign-born youths of humble origin have seized the opportunities presented after their arrival in America, but few have combined such great achievements in physics and engineering with devotion to such high democratic and humanistic ideals and put the whole on record in engaging and inspiring form.

What influences opened Pupin's mind as a youth and brought him to America, his hardships and experiences as a "greenhorn," his entrance to American citizenship and his achievement of a college degree at Columbia; his later studies at the Universities of Cambridge and Berlin, and his professorial and research work at Columbia University, and many things besides, are charmingly told in the first ten chapters of this autobiography. The concluding chapters, on The Rise of Idealism in American Science and on The National Research Council are brimful of suggestion and inspiration. Both of these chapters contain an eloquent plea for scientific research both "pure" and practical. Tributes are paid to the American Society of Civil Engineers and the other three "founder" engineering societies; to the National Academy of Arts and Sciences and to the National Research Council, growing as these two did from the Civil War and the great war of recent years; and particularly to Andrew Carnegie and Ambrose Swasey for their generosity and perspicuity in establishing respectively the United Engineering Library and Engineering Foundation. Other contributors to the promotion of science, both by their own research work and by their benefactions, are not overlooked, nor does the author fail to mention progress in other scientific fields than his own, mentioning in particular progress in biological science in the past twenty-five years.

As an illustration of Prof. Pupin's keen reflections upon many phases of human life and progress, mention may be made of a contrast which he draws in a few sentences between the great industrial work accomplished by Carnegie and by Swasey: The former "achieved great things in mass production," while the latter specialized in the production of "fine machine tools and astronomical instruments of precision."

All through the book notable instances are given of how things seemingly little at the time have a profound influence upon the development of knowledge and character in those who make the best of every opportunity for the advancement of themselves and of the world. It was the chance finding, the immediate purchase and the eager study of a second-hand book from a Paris bookstall that laid the basis for the development many years later of the Pupin inductance coil which has played such a part in the development of telephony during the last two decades. This book was La Grange's "great treatise, 'Mechanique Analytique,' first published under the auspices of the French Academy in 1778." Throughout his book Prof. Pupin refers again and again to his early experiences in the transmission of sound through the earth when he and other herdsmen signaled back and forth by that means.

Prof. Pupin's autobiography is a crowning addition to several most interesting books in this field of literature, that have been reviewed in these columns during the past few years. Like the others, this one can be recommended for reading by any engineer and particularly by students of engineering or of science, or for that matter by any of the youth of the land who are in the formative stages of their career. Many of the persons who within the next few weeks will be racking their brains to think of a suitable holiday present could safely obtain this volume for that purpose, but they should either get the book long enough to read it themselves before giving it away or else purchase two copies.

Addition to Turner on Elasticity

REVIEWED BY GEORGE PAASWELL

Specialist in Mathematical Engineering Problems,
New York City

ELASTICITY AND STRENGTH OF MATERIALS USED IN ENGINEERING CONSTRUCTION: Section III, Theory of Torsion in Shafting and Double Bending of Plates.—By C. A. J. Turner, Consulting Engineer, M. Am. Soc. M. E., M. A. S. T. M., M. Am. Soc. C. E. Minneapolis, Minn.: Published by the Author. Cloth; 6x9 in.; pp. 122; 132 line cuts. \$5.

Section III of the series of texts on elasticity purports to cover the theory of torsion and of double bending. The latter treatment is that given in the book issued jointly by Mr. Turner and the late Prof. Eddy, reviewed in these columns, Feb. 15, 1923, p. 312. But little need be added or retracted from that criticism.

Mr. Turner deserves much admiration for his sincere (and obviously costly) endeavor to bring to the attention of the average designer the more exact treatment of structures by the method of the mathematical theory of elasticity, but one notes with deep regret how unsuccessful a mere qualitative description of stress is. As the reviewer has pointed out previously, no proper description can be given without the aid of mathematics. The reader will not accept fundamental explanations upon the mere say so of the author.

The qualitative description of torsion is ably presented, if one overlooks the annoying intrusions of the author's special terminology, such as rotative and twisting shears. There are three fundamental strains in elastic theory—lengthening, shortening, and shear—and three fundamental stresses—tension, compression and shearing stress. The student can recognize these anywhere. Why confuse him by a special type of name?

St. Venant presented in complete form the exact theory of torsion, analyzing not only the circle, but all types of shapes, and gave an empiric formula that covered almost all cross-sections. Only the circle maintains the plane section during torsion and the old torsion formula is exact for this section alone. The author notes a bulge in the circular section: is that consistent with the demonstration that the circular section is not distorted?

In discussing plate action the author again makes the twisting shear the mysterious force maintaining plate action. This twist is merely a flexural action and the reader need expect no new data on plate action.

A minute's discussion may explain the difficulty in analyzing plate action by the exact theory of elasticity. Upon the simple assumption that Hooke's Law is valid, and upon the continuity of the body, differential equations are built up to be satisfied by the boundary and surface conditions of the deformed body. For the plate,

the data are too complex to lead to any solution of the plate, unless certain approximations are made. A solution can then be found for the circular, elliptical and rectangular plate resting on its periphery, and Michell has extended the solution by means of a theorem in inversion to a plate carrying an isolated load. The flat plate on four columns has not yet received any mathematical solution. Approximations may be found by dividing the surface into convex and concave dishes and applying the formulas for circular plates, properly modified to allow for the terminal bending stresses. This gives a very rough approximation, but it may be a limiting stress condition. The author might well have described some action as above and given the reader a comprehensible idea of plate action; he chose rather to found his analysis on twisting action, to the reader's confusion.

To sum up, while the text may illuminate, in a qualitative sense, torsional and double bending effects, the treatment as a whole can hardly be considered an addition to our knowledge of elastic action in plates.

British Presentation of Sewer Hydraulics

REVIEWED BY JOHN H. GREGORY

Consulting Engineer; Professor of Civil and Sanitary Engineering, Johns Hopkins University, Baltimore, Md.

HYDRAULICS APPLIED TO SEWER DESIGN—By G. S. Coleman, D.Sc. Eng. (London), Assoc. M. Inst. C. E., Associate Member of the Institution of Municipal and County Engineers, Senior Lecturer in Municipal and Sanitary Engineering in the Municipal College of Technology, Manchester, England, and Assistant Lecturer in the same subjects in the Victoria University of Manchester. London: Crosby Lockwood and Son, New York: D. Van Nostrand Co. Cloth; 6x9 in.; pp. 150; 70 line cuts. \$4.

In his preface the author says, "The following pages are founded on notes of lectures delivered to third-year students sitting for the B.Sc. Tech. degree in Municipal and Sanitary Engineering in the Victoria University of Manchester, and also on notes collected by the author from his own practice as a municipal engineer for the past twenty-five years." In its present form the book is by no means a textbook for students in sanitary engineering, nor is it a brief treatise for the practicing engineer. Apparently it is an attempt on the part of the author to put in printed form the main essentials of hydraulics, applied to sewer design, as they appear to him.

From the standpoint of American practice the book is of little value, and as for considering the subject of hydraulics, some phases are not even mentioned, as velocity head, loss of head at entrance, and discharge through orifices. With some of the author's statements the reviewer ventures the opinion that engineers may not agree. For example, in discussing discharge formulas for channels the author says, "It is usual to allow a limiting average velocity of 3 ft. per second in vitrified sewer pipes and from 2 to 1 ft. per second in large sewers, the smaller value applying to the largest sizes. Sewers should never be put under pressure unless constructed of metal pipes." Engineers interested in the rational method of estimating storm water runoff will, however, find a brief but interesting discussion of this subject, especially as regards the time of concentration along a main sewer of the runoff from contributing areas.

The book is well printed and bound, but the illustrations are not well executed. An index is included. The sum of \$4 net is far too high for the material presented.

Chief of Engineers of the Army

THE OFFICE OF THE CHIEF OF ENGINEERS OF THE ARMY—Its Non-Military History, Activities, and Organization—By W. Stull Holt. [Institute for Government Research, Service Monographs of the U. S. Government, No. 27.] Baltimore, Md.: Johns Hopkins Press. Cloth; 6x9 in.; pp. 166. \$1.

No branch of the government has a more honorable history than the Corps of Engineers. Certainly every civil engineer, whether in military or civilian life, should be acquainted with that history. This book, issued as one of the series of the service monographs of the United States Government, is an excellent unprejudiced statement of the Corps' duties and performances. Appendixes give summaries of the laws under which the Corps of Engineers functions, financial summaries, statistics of floating equipment and a bibliography.

PUBLICATIONS RECEIVED

THE REPORT AND RECOMMENDATIONS on a Physical Plan for a Unified Transportation System for Chicago, abstracted in our issue of July 19, 1923, p. 104, may now be obtained from the Bureau of Statistics and Municipal Reference Library, City Hall, Chicago, Ill.; \$2.25 postpaid.

POWER TEST CODES, a Test Code for Hydraulic Power Plants and Their Equipment, has been published by the American Society of Mechanical Engineers but distribution has been held up pending a decision as to whether a revised edition, to include certain changes, will be substituted for the present edition. (American Society of Mechanical Engineers, 29 West 39th St., New York. 70c. to members; 80c. to others; 25 or more copies, 65c.)

BOILERS used exclusively for low-pressure steam heating, hot water heating, and hot water supply are covered in Section IV of the American Society of Mechanical Engineers Boiler Code, 1923 edition. This part of the code has been entirely rewritten since the 1918 edition and as now presented it includes rules governing the construction and operation of steel and cast-iron boilers. (New York; 80c. per copy, 70c. to members; 25 or more copies, 65c. each.)

THOSE WHO FREQUENTLY USE mathematical tables and formulas in practical work, including the geometer and physicist, will find "Synopsis of Applicable Mathematics: with Tables," by L. Silberstein, Ph.D., a convenient volume. The Tables are logarithms of numbers and of the trigonometric functions, and special tables, such as elliptic integrals and the Bessel function. The formulas are the applicable formulas of algebra, geometry, trigonometry and calculus. Non-euclidian geometry is taken up and special attention is given to vector geometry, the quaternion, and tensor calculus. (First published September, 1922, as "Bell's Mathematical Tables"; Reissued April, 1923, as "Synopsis of Mathematical Tables." Printed in Great Britain by Neill & Co., Ltd., Edinburgh. New York: D. Van Nostrand Co.; \$4.50.)

IN THE ROUTINE OF DRY GOVERNMENTAL REPORTS a decidedly unusual degree of interest attaches to a pamphlet just issued by the U. S. Department of Agriculture, under the title "Timber: Mine or Crop?" It is a comprehensive review of the lumbering situation and forest stock of the country, supported by a surprising mass of data on growth, cut, consumption and waste. As a short and easily digestible historical review of the development of American forest exploitation, and of the tremendous changes that have come upon different lumbering states in the course of this exploitation, the engineering reader will find it of particular value. The progress of the center of lumbering from New England to the Lake states, then to the South and now to the West, is outlined; the ruin that has descended upon many sections, such as parts of Pennsylvania and Michigan, through non-conservative exploitation of forest resources, is illustrated; finally, proof is given

that unless wasteful exploitation is stopped and at the same time forest growth is multiplied several times by the adoption of sounder cultural methods, the country will be without a sufficient wood supply in the not far distant future. Not least interesting in all this material are various sidelights on subordinate phases of the general problem such as the menacing part played by the retail lumber dealer in profiteering in our wood resources and the unfortunate influence of decreased water transportation of lumber. There can be little doubt of the importance of the recommendations of the report, whose alternative, the text concludes, "is idle forest lands and timber bankruptcy."

THOSE INTERESTED IN SHORE PROTECTION will find the latest Report of the New Jersey Board of Commerce and Navigation on The Erosion and Protection of the New Jersey Beaches of considerable interest. The report itself is brief, consisting of an outline of the methods followed by the engineering advisory board and its recommendations, but the appendixes are very full. They include an historical account of the changes in the New Jersey shore line, the general principles of coast protection, illustrations and descriptions of beach protective devices, a discussion of action of winds, currents and littoral drift, practice in beach protection in other places, and an outline of the New Jersey laws concerning riparian lands as affected by erosion. The report also contains a set of large scale maps of the New Jersey coast showing the changes in the above line during the past century.

WATER SUPPLY PAPER 494, an Outline of Ground-Water Hydrology, with Definitions, prepared by Oscar E. Meinzer, has been issued. (One copy free, U. S. Geological Survey, Washington, D. C.)

THE LATE WAR delayed completion of the Report on the Study of Fifteen Representative Sewage Treatment Plants, by H. H. Wagenhals, E. J. Theriault and H. B. Hommon, recently issued as Bulletin 132 of the U. S. Public Service. (Washington; paper; pp. 257; one copy free on application, as above; additional copies at 50c. from Superintendent Public Documents.) The plants studied are located at Alliance and Canton, Ohio; Atlanta, Ga.; Fitchburg, Mass.; Lexington, Ky.; Columbus, Ohio; Rochester, N. Y.; Baltimore, Md.; Reading, Pa.; Houston, San Marcos and Sherman, Texas. One-story and Imhoff septic tanks, contact beds, trickling filters and Riensch-Wurl screens in various combinations and (in Texas) activated-sludge process were studied. The plants are described and the results of analyses, made by the investigators for this report, are given. The report is so unique and valuable that every engineer engaged in sewage-works design or operation should obtain a copy.

THE ENGINEERING EXTENSION SERVICE of Purdue University, Lafayette, Ind., has issued a bulletin on Electric House Pumping Systems, by Professors G. C. Blalock and D. D. Ewing.

A.S.T.M. TENTATIVE STANDARDS, 1923, covering 170 subjects, is now available. (American Society for Testing Materials, 1315 Spruce St., Philadelphia; 859 pp.; \$7 in paper or \$8 in cloth.)

THE AUTOMOBILE, improved highways, the wanderlust and the desire to "camp out" make opportune a Florida State Board of Health Bulletin on Tourist Camps, their Sanitary Control and Operation, by George W. Simmons, Jr., chief sanitary engineer (Jacksonville). Revised camp rules are included.

Foreign Papers and Reports

THE EXCELLENT WORK of the Newcomen Society (H. W. Dickinson, secretary, The Science Museum, South Kensington, London, S.W. 7) "for the Study of the History of Engineering and Technology" is continued in Transactions, Vol. II, 1921-22. Among the papers included are: The Early History of Mechanical Handling Devices, by G. F. Zim-

mern; Greek and Roman Engineering Instruments, by R. C. S. Walters; and Mechanics and Engineering from the Time of Aristotle to that of Archimedes. Other papers deal with early railway and locomotive matters, steam navigation, etc. A short analytical biography of the History of Engineering and Applied Science, 1900-1920, is included. A number of interesting old cuts are reproduced. Membership in the society is open to all interested anywhere.

SEWAGE RESEARCH STUDIES at Moscow, 1903-22, are the subject of a 32-p. pamphlet printed in Russian, but with a résumé in French, by S. Stroganoff, chief of the sewage laboratory of the city of Moscow.

New Books and Revised Editions

DESIGN OF CONCRETE STRUCTURES—By Leonard C. Urquhart, Assistant Professor in charge of Structural Engineering, Cornell University; and Charles E. O'Rourke, Assistant Professor of Structural Engineering, Cornell University. New York: McGraw-Hill Book Co., Inc. Cloth: 6x9 in.; pp. 452; 166 line cuts. \$4.

THE DESIGN OF DIAGRAMS FOR ENGINEERING FORMULAS AND THE THEORY OF NOMOGRAPHY—By Laurence I. Hewes, B. Sc., Ph.D., M. Am. Soc. C. E., Deputy Chief Engineer, U. S. Bureau of Public Roads; and Herbert L. Seward, Ph.B., M.E., M. Am. Soc. M. E., Associate Professor of Mechanical Engineering, Sheffield Scientific School, Yale University. New York: McGraw-Hill Book Co., Inc. Cloth: 9x12 in.; pp. 111; 83 line cuts. \$5.

EISENERÜCKENBAU—Dritter Band. Die Hauptträgersysteme. Nebst ihrer Berechnung. Bauliche Einzelheiten Der Balken-Bogen-Und Hängebogenbrücken. Bauliche Einzelheiten Der Hängebrücken. Herstellung Der Eisenbrücken In Der Werkstatt Und Auf Der Baustelle. Von George Christoph Mehrrens, Geh. Hofrat und Professor der Ingenieurwissenschaften an den Technischen Hochschule in Dresden. Leipzig: Wilhelm Engelmann. Paper: 7x10 in.; pp. 435; halftones and line cuts.

"HÜTTE": TASCHENBUCH FÜR EISENHÜTTENLEUTE—Herausgegeben vom Akademischen Verein Hütte. E. V. Berlin. [Dritte Durchgesehene Auflage.] Berlin: Wilhelm Ernst & Sohn. Cloth: 5x7 in.; pp. 963; 511 line cuts.

HYDRO-ELECTRIC POWER STATIONS—By David B. Rushmore and Eric A. Lof. [Second Edition.] New York: John Wiley & Sons, Inc. Cloth: 6x9 in.; pp. 830; 437 halftones and line cuts. \$7.50.

INDUSTRIAL OIL ENGINEERING—By John R. Battle, M.E., C.E., Assoc. A. I. S. M. E., M. Engineers' Club of Philadelphia. [Second Revised Edition.] Philadelphia: J. B. Lippincott Co. Cloth: 6x8 in.; pp. 1141; 400 halftones and line cuts, 9 charts, 9 colored plates. \$10.

POPULAR FALLACIES EXPLAINED AND CORRECTED (with copious references to authorities)—By A. E. Ackermann, M. Assoc. Consulting Engineers, Assoc. M. Inst. C. E. [Third Edition.] London: The Old Westminster Press. Cloth: 6x8 in.; pp. 384.

PRACTICAL CONTROL OF ELECTRICAL ENERGY—By Alfred George Collis, A. M. I. E. E., M. Am. I. E. E. [Oxford Technical Publications.] London: Henry Frowde and Hodder & Stoughton; New York: Oxford University Press. Cloth: 6x9 in.; pp. 169; 142 halftones and line cuts. \$3.50.

Intended to give "descriptive technical data of the design of electrical apparatus and machinery, as applied to everyday practice," and to explain and solve "alternating and direct current problems intelligently without the introduction of complications and formulas."

THE PREVENTION OF VIBRATION AND NOISE—By Alec B. Eason, M. A. (Cantab.), Assoc. M. Inst. C. E., A.M.I.E.E. [Oxford Technical Publications.] London: Henry Frowde and Hodder & Stoughton; New York: Oxford University Press. Cloth: 6x9 in.; pp. 163; 65 halftones and line cuts. \$3.

STRENGTH OF MATERIALS: Prepared in the Extension Division of the University of Wisconsin—By Walter E. Wines, Assistant Professor of Mechanical Engineering, University of Wisconsin. [Engineering Education Series.] New York: McGraw-Hill Book Co., Inc. Cloth: 6x9 in.; 103 halftones and line cuts. \$2.25.

A TREATISE ON ENGINE BALANCE USING EXPONENTIALS—By P. Cormac, Fellow of the College of Science for Ireland, Demonstrator in Mechanical Engineering at the College of Science, Dublin. Lecturer in Heat, Electricity and Motor Car Engineering at the City of Dublin Municipal Technical Institute, New York: E. P. Dutton & Co. Cloth: 6x9 in.; pp. 131; 55 line cuts. \$8.

THE WELDING ENCYCLOPEDIA: A Practical Reference Book on Autogenous Welding—Compiled and Edited by L. B. MacKenzie and H. S. Card of the Editorial Staff of The Welding Engineer. [Third Edition.] Chicago: The Welding Engineer Publishing Co. Cloth: 6x9 in.; pp. 360; many halftones and line cuts, some colored plates. \$5.

This (the third) edition of a book first published in 1921 contains a new chapter on training oxy-acetylene and electric arc welders, and additional matter on welding tanks and pipes.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Responsibility for Timber Treating Inspection

Sir—Within two years, we have had two failures on the part of inspection bureaus to detect failure on the part of plant management to live up to the specifications on creosoted timbers. In one case the quality of timber was involved; in the other, exact lengths. This concerned the same contractor, but different treating companies and different inspection bureaus.

Our contract provides that progress inspection does not relieve the contractor of responsibility for defects discovered at a later time. The extra expense incurred by the contractor was not relatively large but there was also delay and annoyance. The treating company in each case claimed that when we sent an inspector the responsibility rested with the inspector while the inspection bureaus each stated that the current rates for such inspection are so low that it would be suicidal to guarantee such details of inspection as were involved, or to make good any losses incurred by the contractor.

A recent conference in this office with the three interests involved in the last case seemed to bring out the fact that there should be either less responsibility placed on the inspection bureau and therefore more on the treating plant management, or else more on the inspection bureau with the plant management and contractor relieved from all subsequent responsibility.

The question of equity seems somewhat involved. When the county employs an inspection bureau whose representative passes on the material and treatment at the plant, and it later develops that there has been a failure to comply with the plans and specifications, should the county, acting through an inspection bureau as its agent, be responsible to the contractor, thus waiving the clause in the contract touching on progress inspection?

No doubt this question has arisen in other instances, and I should be glad to have an expression from others in regard to the equities involved.

V. R. COVELL,
County Engineer,
Allegheny County.

Pittsburgh, Pa.

Making Contract Bids More Certain

Sir—The article "Overlooked Items in Estimating Road Work" in *Engineering News-Record* Sept. 6, 1923, p. 391, holds a great deal that is applicable to construction contracts in general. The item set forth in the first paragraph of the subtitle, "General Factors," and more definitely estimated as 15 per cent as the minimum that should be added to cover risks embraced in the so-called "Unilateral Contract" usually submitted by the owner, is a puzzling item for most construction contractors.

Contractors frequently submit alternate bids for doing work of construction through the use of substituted materials or equivalent procedure. Why not submit alternate forms of agreement to the owner? The contractor is in a position to form his agreement so as to reduce these hazards: (1) Acts of God; (2) delays and suspensions of work by owners; (3) unusual increase or decrease in contract quantities; (4) absence of means for legal redress for injustices or arbitrary decisions, and (5) the unilateral form of contract, under which one is generally compelled to bid and by which the contractor may be penalized for one or all of the above contingencies.

Items 1 and 4 are frequently but little understood by either contracting party as to the legal decisions affecting these terms when used in the uniform contract.

Items 2 and 3 are frequently the cause of disputes for which the clause in the contract provides a committee or referee. The unilateral form of contract is in a sense a misnomer, as it presumes the doing of an act in reliance upon the promise of another. This term, "unilateral," is a technical term distinguishing a contract of this nature from a so-called bilateral contract, where the promises and performances are said to be mutual.

Now, a word in closing as to the term "penalties," which is very misleading. Where the owner and contractor agree upon certain sums to be paid on breach of the contract (by either) it may be recovered if intended as liquidated damages for non-performance, but the weight of decisions by American courts shows that penalties will not be enforced and recovery is limited to the loss actually sustained.

In view of the conflicting laws of the various states, it is impossible to reconcile the use of the uniform contract in its present form without reference to the state decisions where the construction contract is to be performed. A saving of 10 per cent is worth while by either owner or contractor if this can be done through the substitution of an alternate form of agreement which will allow "bids to be more definite" and assure completion of construction without actual or threatened litigation.

HORACE H. SEARS,

Consulting Engineer and Attorney at Law.

New York City, Oct. 6, 1923.

"Sand-Hogs" or "Sand-Braves"

Sir—Occasionally there is in the daily press an expression or phrase that may be without a worthy origin and therefore a subject for comment. Engineering affairs are involved.

In deep foundations and caissons in the present state of the art employees are frequently obliged to work where health and life are in constant peril. Why are such laborers so often called "sand-hogs"? Apparently the words are a misfit. If not rude or harsh as some might argue, since no repugnance is felt by employer or scribe, still the last word implies a condition and sundry activities that have been fostered by man through irregular feeding and want of care. In nature the pig is an exceptionally neat creature, no more intent upon food than many other mammals, and it is far from being without wit or good sense. Besides in sterling ancestry the pig can claim distant kinship with the mighty mammoth of the past and the elephant of today as we have all known since a London meeting of the Royal Society about the year 1876 when it was declared that,

"A very tall pig with a very long nose
Sends out a proboscis quite down to his toes
And thence by the name of elephant goes
Which nobody can deny."

The papers say that many of the workers come from the West Indies. Kinship there has not been free from man's influence. Perhaps an early forbear was in "the fifty-foot boat" that astonished Columbus off the Honduras coast. It required stamina to endure the civilization of the white race for four hundred years whether the sufferers were of American or African descent. And today the man who passes the physician's test and works under an air pressure of 40 lb. in a temperature of 130 deg. F. must possess some qualities of value to the human race and might well be envied by groups of men who spend much time looking for a soft place and never get below the surface of things.

Courage that results in convenience to the public passes unnoticed while admiration for an inferior sort exhibited in the prize-ring is limitless. In caisson work as in many other kinds of employment there is opportunity for different degrees of intelligence and for quick action. Was not the workman who was driven through the roof of a tunnel and 30 ft. of water by an air bubble rushing to stop a leak?

If *Engineering News-Record* were to suggest that "sand-braves," harking back if you please to tribal times, would be a just replacement there is little doubt but that the press would quickly follow its lead.

H. F. DUNHAM,
Civil Engineer.

New York City,
Nov. 1, 1923.

More on Duty of Water Tests

Sir—The very interesting paper on "The Economical Use of Irrigation Water Based on Tests," which appeared in *Engineering News-Record*, Oct. 4, 1923, contains a slight error under the discussion of the authors' Case 2. The error does not fundamentally affect the purpose of the paper but it is believed that it should be pointed out on account of its mathematical significance.

Near the bottom of the first column, page 550, in discussing the situation which arises when $\frac{b}{a}$ is less than the value of the y - w curve for zero water application, the following statement is made, "Should there be a point of inflection on the curve, which is very improbable, a tangent

P-w CURVES COMPUTED FROM Y-w AND Y'-w CURVES FIG. 4

may be drawn through P_2 to the curve as shown on the y - w curve in Fig. 4, thus showing that a solution would then be possible."

The last clause of this statement is incorrect, as should be readily apparent from the fact that the "tangent" referred to crosses the y - w curve. A horizontal tangent to a curve does not necessarily indicate a maximum point on the curve. It may designate either a minimum or a maximum, or neither.

The situation in the present case may be illustrated by constructing a profit-water (P - w) curve, as in the accompanying diagram. The point of tangency to the y - w curve in Fig. 4 corresponds to the flat place shown in the P - w curve at A.

It happens that the point chosen for P_2 in Fig. 4 is such that a tangent can be drawn through the point of inflection on the y - w curve. If a slightly higher location had been chosen for P_2 , then a tangent might have been drawn to either the convex upward part or the convex downward part of the y - w curve, in which case the P - w curve would have been of the general form shown dotted in the diagram, the two tangents designating the temporary maximum and minimum points B and C respectively.

In the paragraph immediately preceding the sentence quoted above the authors state that when $\frac{b}{a}$ is less than y "it means that a profit may be obtained from dry-farming, which is contrary to the conditions considered in this case." This statement closes the matter and the discussion should have been carried no further.

It is believed that it would be much safer in all cases to find the peak of the profit-water curve by actually constructing that curve rather than by the indirect y - w curve method illustrated. This applies especially to complicated areas where many kinds of crops are to be grown.

It is mathematically demonstrated in the paper that the point of tangency shown on the y - w curve in Fig. 4 corresponds to a maximum point on the P - w curve, but this same fact is illustrated more clearly by the summit in the profit curve at C, in the accompanying diagram. The P - w curve also presents a picture of the actual profits, which the y - w curve-tangent method does not do. A maximum profit point located by the latter method for Case 2 or 3

without a proper understanding of the system may prove upon investigation to be a "minimum loss" point.

Denver, Colo.,

Oct. 11, 1923.

JULIAN HINDS,

Engineer, Bureau of Reclamation.

Composition Core-Walls Suggested by Apishapa Dam Failure

Sir—The failure of the Apishapa Dam in Colorado, described in *Engineering News-Record*, Sept. 13, 1923, p. 418, illustrates anew the hazards involved in the construction of earth-fill dams which have no special provision for preventing excessive percolation or flow of water through the dam. Sprinkling and rolling of the fill material may not always be sufficient to provide a reliable structure, and the factor of safety of such a dam may be lamentably low.

The logical way of obtaining a satisfactory structure is the application of what one engineer has called "the great hydraulic principle": Construct one impervious surface, and build the rest of the structure to support that surface. Accordingly, clay puddles, masonry and concrete core-walls, etc., have been successfully used for many earth dams. In a discussion of a paper on the design of earth dams (Proc. Am. Soc. C. E., Sept., 1923, p. 1616) the writer described a somewhat novel type of impervious diaphragm, or composition core-wall, which is in full accordance with the "hydraulic principle" and at the same time costs but little. This composition core-wall is made of two slabs of reinforced gunite with a layer of asphalt between, and it extends at a slope of about $1\frac{1}{2}$ to 1 from the impervious foundation material to the crest of the dam. While it is desirable to place selected fine material against the diaphragm on the upstream side, the main portion of the fill may consist of ungraded material, and much less care than usual need be given in placing and rolling this material, inasmuch as the composition diaphragm is so flexible that it may be expected to adjust itself elastically to almost any settlement that may occur in an earth dam. Such composition core-walls should be built on an incline inasmuch as the material overlying the diaphragm will then always keep the asphaltum under compression. Furthermore, no forms are needed and the diaphragm may be conveniently built up without interfering with the work on the main fill. The upstream face of the dam should be protected against wave action by gravel, riprap, or a slab of reinforced gunite, preferably provided with weep-holes.

Inasmuch as the composition core-wall is buried in the body of the dam it is well protected against damage from temperature or other external influences, and it may be expected to last indefinitely. As regards impermeability of this type of core-wall, it is well known that gunite is remarkably watertight, and the layer of asphalt between the gunite slabs will give additional assurance against leakage. It is of importance, however, to secure a safe contact between more or less impervious foundation material and the core-wall both along the base of the dam and on the side abutments.

The water rising in the reservoir will first come in contact with the selected fine material overlying the diaphragm so that saturated clayey material, and not the water directly, will press against the diaphragm. This is obviously a great advantage as compared with a concrete slab on the upstream face of the dam, sometimes used.

For comparatively low embankments the composition core-wall may be made of two 1-in. slabs of gunite and one layer of asphalt. For higher structures two or more 2-in. slabs with a corresponding number of asphalt layers may be used. It is estimated that in average cases the cost of such composition core-walls will amount to about 40 to 50c. per square foot. The saving in placing the fill material, the reduced seepage losses through the dam, the protection against burrowing animals, and the greatly increased factor of safety of the dam should more than compensate for the cost of such a composition core-wall, and failures like those of the Apishapa Dam would be very unlikely to occur.

Los Angeles, Calif.,

Oct. 20.

FRED A. NOETZLI,

Structural and Hydraulic Engineer.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

A Dinner in Honor of Charles M. Schwab will be given Nov. 20 by the Engineers' Club of Philadelphia to which Mr. Schwab was elected an honorary member last June.

Contract for a Portion of the Baldwin water filtration plant, at Cleveland, Ohio, including filter and administration buildings and seven gate-house structures, has been awarded to the Strange-Walsh Construction Co., of Cleveland, at \$2,885,500.

According to Recent Press Dispatches, the Pennsylvania R.R. plans to electrify a portion of its system over the Allegheny Mountains. The power for this electrification is to be developed at steam generating plants located at the coal mines. It is probable that the portion of the system referred to is the four-track main line between Johnstown and Altoona.

The Third Annual Ohio Conference on water purification with the Ohio Department of Health will be held at Columbus, Ohio, Nov. 21 to 24. Besides numerous papers and topical discussions visits will be made by automobile to see the water purification and softening plants at Newark, now nearing completion, and at Delaware, in service for a year.

Missouri Road Construction Progress is announced by the state highway department as follows: 2,032 miles of the 7,640-mile state highway system completed to Oct. 13 at an estimated cost of \$25,284,000, of which 1,018 miles are graded earth, cost \$7,096,000; 717 miles gravel, \$6,384,000; 48.06 macadam and asphalt, \$978,000; and 249 miles concrete and brick, \$9,034,000. Bridge work and culverts have cost \$1,792,000.

The Survey of the Power Resources of the valley of the Tennessee River, which is being conducted by the Corps of Engineers, will not have reached a point where reports on the Finch and Power Rivers will be ready for at least a year. This means that the Federal Power Commission will not be able to pass upon the application of the Knoxville Power & Light Co., the Tennessee Electric Power Co., and the Tennessee Hydro-electric Co., before that time.

The Secretary of War Has Requested an additional appropriation of \$2,000,000 to cover the installation of four more units of electrical equipment at Muscle Shoals. The plan had been to install at first four 30,000-kw. generators. The structures are being built with the idea of accommodating eighteen units ultimately. The decision to install eight units at the start is thought to indicate confidence on the part of Secretary Weeks that a market will be found for a portion of the secondary as well as the primary power.

Railroad Construction Program to Be Continued in 1924

The enormous construction program of the railroads of this country which was started in 1923 will be continued in 1924, according to an announcement of the American Railway Association. The total expenditures for this year will amount to \$1,059,440,000 and the unexpended balance appropriated for new work which will be carried over into 1924 amounts to \$243,804,000, which, with the \$429,273,000 spent in 1922, makes a grand total of \$1,732,517,000 spent in capital improvements since the railroads started their reconstruction and extension work in 1922.

Canal Bureau Investigation Ends

Judge Joseph A. Kellogg, appointed by Governor Smith to conduct an investigation into the canal bureau of the state department of public works under the Moreland act, has ended his investigation and is engaged in the preparation of a final report which will be submitted to the Governor soon after Nov. 20.

Royal K. Fuller, deputy superintendent of public works, in charge of the bureau of canals and waterways, is said to be in favor of the abolition of the office of division engineer and the undertaking of all dredging operations by contract. Mr. Fuller favors bringing the entire barge canal system to a mean depth of 12 ft. and undertaking dredging in the spring to bring this about.

Observers of the situation look for a general shakeup in the personnel of the barge canal force at an early date.

How Bureau of Reclamation Is Reorganized

Detail announcement of the changes in the Bureau of Reclamation briefly announced last week (p. 777) sets forth the complete separation of engineering and project operation, the latter including settlement of the projects. The field commissioner of the bureau is to be in charge of operation, including water service, collection, settlement and development problems. Project managers will report to the field commissioner on these matters and to the chief engineer on engineering matters. The engineering department is restricted to the investigation of proposed projects, the designing of irrigation works, and their construction. Both the field commissioner and the chief engineer are to be subordinate to the commissioner of reclamation. Minor departmental changes in the Washington office are also ordered, which, the announcement of the Interior Department says, "make a net saving of \$10,000 a year on salaries alone." The reorganization of the field service is to become effective Jan. 1.

Many Bond Issues Voted Upon November 6

Pennsylvania Roads Get \$50,000,000—
Virginia Rejects \$50,000,000
Issue—Other Projects

Bond issues for public improvements and constitutional amendments proposed to facilitate public works construction were not surprisingly extensive as recorded by voters throughout the country at the general elections held Nov. 6. Decided antipathy to raising the debt limit or to increasing bonded indebtedness was apparent in some sections of the country, while in others large issues were authorized or municipalities were empowered to extend debt limits in order to provide for increased sewerage, water-works and general municipal facilities, or provide for street and road work and public buildings and bridges.

The State of Pennsylvania authorized, by an amendment to the state constitution, an increase of \$50,000,000 in the amount the state assembly is empowered to appropriate for road-building purposes. The money will be available only after the assembly provides for the issuance of bonds, and they are sold. As the next session of the assembly does not convene until January, 1925, the \$50,000,000 will not become available until the construction season of that year. The amendment was approved by a vote of about four to one.

The only other large state highway issue voted upon, one of \$50,000,000 proposed for the completion of Virginia's primary highway system, was overwhelmingly repudiated by the voters of that state.

PHILADELPHIA LOAN APPROVED

Voters of Philadelphia approved the municipal loan of \$67,250,000, to be provided in 50-year bonds, the money to become available after the city council has passed enabling acts for each specific appropriation. The largest items in this loan are: Delaware River bridge, \$5,623,000; sewage-disposal plants, \$9,000,000; water supply, \$6,000,000; sewers, \$3,300,000; high-speed subway, \$15,000,000; surface car subway, \$10,000,000; damages for street openings, \$5,077,000; and port development and art museum, \$2,000,000 each. Although most of this money will not be available until March, 1924, construction of the Delaware River bridge can be carried forward on the basis of funds authorized as soon as enabling acts can be provided by the city council.

Philadelphia also authorized a municipal loan of \$3,750,000 of 15-year bonds for road improvement in the city, police signal equipment, improvement of the county institution for the feeble-minded and the construction of a surface car line. Road improvement will take about \$2,400,000 of the total, and the money will be available about March 1, 1924.

Voters of Chicago authorized the city to levy an additional 25c. per \$100 of assessed property value for school construction and the acquisition of school sites; (2) to issue bonds in the sum of \$2,650,000 for constructing the proposed La Salle St. bridge; and (3) to issue \$2,000,000 in bonds for establishing, enlarging and improving parks and boulevards under control of the West Chicago Park Commissioners. The tax for school purposes, it is believed, will raise in the neighborhood of \$4,250,000 yearly.

Baltimore was authorized to issue \$10,000,000 in stock of the municipal corporation for water-works improvements. Work will consist largely in extending mains into new territory, and in the purchase of private plants within the city limits. It is planned to use \$2,000,000 of the money each of the next five years, and sale of the first issue is expected to take place within 90 days. Baltimore was also authorized to provide \$1,000,000 for new police department buildings.

CINCINNATI REMEDIATES ISSUES

Cincinnati was one city wherein bond issues for public improvement were overwhelmingly defeated. The five issues proposed, but against which at least five to three votes were returned, were: Extension and extending Fifth St., \$1,850,000; city's share of bonds for Eighth St. viaduct, \$850,000; sewer extensions, \$650,000; park system, \$1,750,000; and Canal Boulevard, \$3,300,000. Hamilton County, Ohio, also defeated \$2,500,000 proposed public library bonds.

It is also interesting to note that the voters of Cincinnati rejected a proposed city ordinance to limit the speed of motor-driven vehicles by the installation of automatic governors. It was proposed to install and seal speed-regulating devices to hold vehicles to a 25-mile maximum.

A bond issue of \$5,000,000 for a sewage disposal plant and necessary relief, storm water and interceptor sewers was passed by the city of Grand Rapids, Mich. Sewer construction to the amount of about \$800,000 will be undertaken in 1924. The disposal plant will probably not be started until 1925.

Two amendments to the city charter of Detroit provide money for public improvements. The first raises the city's bonding limit from 6 to 9 per cent, and provides for the issuance of bonds as follows: water-works, 2 per cent of all real and personal property in the city; electric light and power, 1 per cent; other public utilities, 2 per cent; all other lawful purposes, 4 per cent; the total not to exceed 9 per cent. This bonding limit amendment, which required a 60 per cent favorable vote, received 62 per cent.

What is considered more important was the Detroit charter amendment which paves the way for rapid transit by allowing the city to bond up to 4 per cent of its assessed valuation for such purposes. This proposition also required a 60 per cent favorable vote, but received one of 67 per cent. The city is given authority to proceed with plans for the construction of a rapid-transit system. On the basis of the present valuation of the city's property \$80,000,000 may be so issued. The amendment also provided for a sub-way board of three members each to

Will Buy Distribution System of Montclair Water Co.

On Nov. 6 the town of Montclair, N. J., voted to buy the distribution system and other local property of the Montclair Water Co., or if that cannot be done then to build a distribution system. The vote to purchase was 3,860 to 1,852, and the vote to build a new distribution system, if need be, stood 1,467 to 4,483. The corresponding majorities were 1,852 and 3,016.

Prior to the election it was announced that the Montclair Water Co. had offered to sell all its property within Montclair, used for local supply purposes, for \$1,700,000, retaining its share in the Little Falls pumping and filter plant and the other property owned jointly by the East Jersey Water Co. and associated companies. It was also announced that Montclair had applied to the North Jersey District Water Supply Commission for a right to 3 m.g.d. in the Wanauke supply being developed by the commission under a contract with Newark, and that the Newark authorities had agreed to exchange this water right for the same quantity of Pequannock water, and that pending the completion of the Wanauke works, some three years hence, Newark would sell Pequannock water to Montclair at \$90 per m.g. The expectation is that the purchase of the distribution system will be consummated at an early day and that immediately thereafter a connection will be made with the Newark-Pequannock conduit.

By means of these contracts and changes Montclair will effect a change from the filtered Passaic River to which there has been increasingly strong local objection during the past few years. A feature of the campaign against this supply was the B. Welchii incident, treated at length in these columns.

receive a salary of not less than \$10,000 yearly.

Another important construction project which was considered Nov. 6 was a proposition set before the voters of Toledo, Ohio, whereby \$3,000,000 in bonds was to be used for grade elimination work. Though the measure received a large majority of favorable votes it was lost through failure to receive a two-thirds vote. However, it is probable that inasmuch as the electorate returned a majority in favor of grade elimination the work will be done through other means.

Several bond issues for road and bridge construction and others for building schools, were reported. In Oregon bridges are provided as follows: Sellwood bridge (near Portland), \$350,000; Albany bridge, \$294,976; and Harrisburg bridge, \$203,592. All will span the Willamette River, the latter two at the towns named.

Voters of Somerset County, Pa., approved a \$2,000,000 road bond issue.

Other bond issues voted favorably on were: Charlottesville, West Va., \$500,000 for water-works; McKeesport, Pa., \$233,000 and Jamestown, N. Y., \$280,000 for water-works; Massillon, Ohio, \$300,000 for sewers; Warren, Ohio, \$926,000 for schools; Youngstown, Ohio, \$1,000,000 for schools; and Buffalo, \$1,000,000 for a natural science museum.

Scores Injured as Two Temporary Grandstands Collapse

Fifty-eight spectators at a football game between West Virginia and Washington and Lee were injured, though none fatally, in the collapse of a temporary grandstand Nov. 10 in Charleston, W. Va. A score or more were hurt when a like accident occurred at Lewisburg, Pa., during the Lehigh-Bucknell game.

The accident at Charleston occurred when the spectators arose during an exciting moment when the home team was scoring at the far end of the field. The spectators had been seated about an hour. Most of the injuries received consisted in broken legs and sprains. These temporary stands were 200 ft. long and 12 ft. high at the rear and contained seating arrangement for approximately a thousand. Inspection of the stands by a local engineer indicated cross-bracing on the rear of the stands was lacking. No official investigation has been started.

No details on the description of the Lewisburg stand are available at present.

U. S. Senate Committee Views Chicago Projects

Sewage disposal and waterway projects of Chicago and Illinois are being studied by a committee of the U. S. Senate, largely in regard to the city's desire to increase its diversion of water from Lake Michigan to 10,000 cu. ft. per second for the purpose of diluting the sewage flow in the drainage canal. A secondary matter is the establishment of a 9-ft. navigable channel from Lake Michigan to the Mississippi. The drainage canal is 24 ft. deep and the state has started a 9-ft. connection to the Illinois River at La Salle, but the improvement of that river to the Mississippi must be done by the federal government.

At one of the meetings it was stated that the Sanitary District of Chicago has spent \$125,000,000 on sewage disposal works and plans an expenditure of \$97,000,000 within the next twenty-two years to provide for the increasing population. The city's entire program of sewage treatment and disposal is based on the claim that the city has a right to divert a flow of 10,000 cu. ft. per second from Lake Michigan.

French Firm Gets Contract for Port of Athens Work

The contract for the Piraeus Harbor works has been awarded to a French syndicate. The contract involves the expenditure of 200,000,000 drachmas, based on a rate of exchange of 400 to the pound sterling, any difference above or below this to be adjusted in bi-monthly settlements.

The conditions accepted are: 17 per cent compensation of the value of machinery and installations erected for the purpose of the works; 14 per cent for overhead expenses; and 10 per cent profit. Work is to begin this month and is to extend over a period of not more than 8 years. The tender accepted follows generally the specifications drawn by the port committee. There was only one other offer received, from a French-Dutch-Greek group. No American or British offer was received.

Omaha Water Emergency Is Investigated

Report Made on Inquiry Into Cause of Breakdown of Sedimentation Process Last August

Special Correspondence

An unfortunate combination of circumstances apparently was to blame for the emergency by which the water mains of Omaha were filled with mud during the week of Aug. 21. An open investigation was held, starting Oct. 23, by the directors of the Metropolitan Utilities District to ascertain what happened and why. (See *Engineering News-Record*, Aug. 30, p. 364.) Reports were made by C. D. Robison, engineer in charge of operations; R. B. Howell, general manager; F. P. Larmon, chief engineer in charge of construction; George T. Prince, consulting engineer and formerly chief engineer; and A. B. Hunt, superintendent of the Florence station and for forty-three years an employee of the water works.

Mr. Robison's conclusions as to the cause of the breakdown of the sedimentation process through the series of seven reservoirs on which Omaha had depended to get a reasonably clear water, are as follows: (1) Failure to complete the installation of pumps authorized in June, 1922, before the maximum demand in 1923; (2) failure of the operating department to recognize the emergency in time and to use to the utmost the pumping capacity available to wash and fill the basins; (3) a river water of unusually high turbidity (20,000 p.p.m. was reported) at peak demand; (4) an open mud valve which increased the low-service pumpage by more than 2 m.g.d. and made less water available for basin washing and refilling; (5) a broken valve in a bypass around Basin 2 made it impossible to clean this basin until the demand was reduced or the influent from Basin 3 to the new filter plant was completed.

PRINCIPAL REASON GIVEN

Mr. Prince stated that the prime reason for the breakdown of the basin service was the lack of regularity in washing the settling basins. In his opinion the operating department did not fully realize the seriousness of the situation and allowed their fear of the possible breakdown of the machinery to deter them from maintaining the required pumpage into the basins and the proper washing of them. The river water carried about five times as much turbidity as in corresponding months of previous years. Connecting the filter plant with the existing system interfered with the normal operation only seven days and Mr. Larmon stated that "here was ample time (nearly two weeks) after the last interference and before the emergency, for the reservoirs to be cleaned."

Mr. Larmon concluded that the fundamental cause of the breakdown of the sedimentation system was the lack of sufficient pumping equipment to permit washing the basins often enough to cope with the large amount of silt carried by the river.

Mr. Hunt also stated that the principal cause of the breakdown was the delay in ordering new pumps, breakdowns in the old ones for the past two or three years seriously interfering

San Francisco to Have Vehicular Tube Under Market Street

Contract has been awarded by the California State Harbor Commission for a vehicular subway under the Market Street car loops at the Ferry. The tube has been planned to provide a means by which traffic moving along the waterfront can cross the heavy Market Street traffic without delay. The cost of the tube is to be apportioned as follows: Harbor Commission, five-eighths; City of San Francisco, one-quarter; Municipal Ry., one-eighth. Until the franchise of the Market Street Ry. expires, that company will pay 6 per cent interest on one-eighth of the cost.

The tunnel proper will be 330 ft. long, with a 330-ft. approach on a 4 per cent grade at either end. The clear width will be 23 ft. and the height 13 ft. Construction is to begin at once and is to be completed in about ten months. The contract went to the Tibbitts Pacific Co. for \$237,700, and the total cost of the tube including cement, pump pumps, etc., is estimated at about \$330,000.

N. Y. Building Congress Prepares Interesting Program

A program of luncheon meetings for members and friends of the New York Building Congress has been announced. The first will be held Nov. 21, the subject to be winter construction, and special reference will be paid to advantages of winter construction to public departments, real estate interests, property owners, architects, builders, workmen, and material dealers. The January meeting will be addressed by Charles L. Eidlitz, commissioner of the Electrical Contractors Association, on "What the Law Writes into Your Building Contract." Other meetings have been arranged as follows:

February, simplified practice, with special reference to how simplification can be applied to the advantage of the building industry; March, the building congress movement, and what it has done for all elements of the building industry; April, an illustrated lecture on the Japanese disaster; May, an international review of the contribution of organized labor to the building industry; and June, three centuries of American architecture, also an illustrated lecture.

with basin washing, but he cited eight local contributing causes culminating when the river started to cut into a mud bank just above the intake.

The report of the investigating committee found that there was excess pumping capacity not used; that against the orders of the chief engineer a basin with unstable walls was filled and the wall collapsed losing 10 to 15 m.g.d. of water and putting the basin out of service 18 days; that the chemists' requests for basin cleaning were ignored; and, that a mud valve was opened wasting 12 m.g.d. (no one knows by whom). The committee was of the opinion that better operating records should be kept so that those in charge would be advised at all times as to turbidity, necessity of washing and of construction under way but that operation should always be the first consideration.

Walsh Resigns as Head of N. Y. Canals Bureau

Greene Appoints Royal K. Fuller, Former Highway Commission Secretary, to Succeed Him

Edward S. Walsh, Commissioner of Canals and Waterways of the New York State Department of Public Works, twice superintendent of public works under Democratic administration, resigned Nov. 9, the resignation becoming effective Nov. 12. When the law combining the state departments of highways and public works and public buildings became effective, Mr. Walsh was temporary head of the combined departments which bore the title of State Superintendent of Public Works. Commissioner Greene was named by Governor Smith as State Superintendent of Public Works which relegated Mr. Walsh as head of the Bureau of Canals and Waterways.

Upon assuming his new office Colonel Greene instituted an investigation of the public works department, beginning with the canal bureau of which Mr. Walsh was the head.

In a statement to the press concerning his resignation, Mr. Walsh said: "In presenting my resignation as Commissioner of Canals and Waterways to the Superintendent of Public Works, I do so with the full knowledge and belief that I am acting in the best interests of the proposed plan of consolidation of the public works department having to do only with the canal system of this state."

"Not in sympathy with the consolidation act that subordinates the old Department of Public Works to a mere bureau known as the Bureau of Canals, feeling that when that section relating to the maintenance and operation of the canal system of the state was written into the constitution it was not contemplated nor intended that at any time in the future the canals would occupy a secondary place in the consolidation or concentration of state activities, I am confident that the step I am now taking is the proper one."

Colonel Greene has announced the appointment of Royal K. Fuller of Albany, as Commissioner of Canals and Waterways, to succeed Mr. Walsh, resigned.

Mr. Fuller, who was formerly a New York newspaper man, entered the state service in 1913 as secretary of the State Highway Commission. He served as secretary of the Highway Commission in 1913 and 1914 and was reappointed by Colonel Greene in 1919.

Since 1921 Mr. Fuller has been with the firm of Fuller & O'Brien in Albany. This firm has been engaged in the insurance and surety bond business, specializing on highway contract work.

Parkway Tunnel in Philadelphia Under Contract

The Commissioners of Fairmount Park in Philadelphia, on Oct. 31, awarded a contract to Andrew O'Neill, Philadelphia, for construction of three sections of the surface car tunnel under the Parkway. The contract price is \$166,000. The work includes construction of the portion of the tunnel directly beneath the Parkway roadway, and will permit of completion of the roadway at this point.

Rail Bridge and Building Men Meet

Prominent subjects at the annual convention of the American Railway Bridge and Building Association, held at Seattle, Wash., in October, included the advantages and disadvantages of concrete tanks, a comparison of culvert materials, renewals of ballasted-deck timber trestles and the methods of installing culverts under traffic.

In a paper on "Concrete Tanks for Railway Water Service," C. R. Knowles, engineer of water service, Illinois Central R.R., stated that watertight concrete can be made but that there is need for uniform or standard designs of tanks to reduce the cost, as at present the first cost does not compare favorably with other materials. Both concrete pipe and cast-iron pipe for culverts were approved in a committee report, the selection being governed largely by local conditions. There is said to be a tendency towards the use of concrete pipe on account of lower cost of installation. That ballasted-deck timber trestles under repair are usually found in worse condition than indicated by the inspector's report, was stated in a committee report which also described different methods of carrying out renewals of ballasted decks. Another report presented various methods of installing and renewing culverts and pipe lines in railway fills under traffic by means of tunneling and trenching and by jacketing or jetting pipes horizontally through the solid fill.

A uniform painting program covering the entire year and enabling a permanent force to be maintained is practicable and economical, according to a committee report, and the arrangement of such a program was presented in a paper by T. R. Wyles, vice president of the Detroit Graphite Co. Detailed lists of tool equipment for bridge and building gangs and water service gangs were presented by another committee, together with notes of special equipment for the latter gangs. Other reports dealt with water facilities at stock yards and the heating of small passenger stations. The organization and management of railway bridge and building forces was the subject of a paper by George W. Rear, bridge engineer, Southern Pacific Ry.

Addresses on general railway matters included "Railways as Investments," by G. T. Reid, vice president of the Northern Pacific Ry., and "Relations of Railway Employees to the Public" by M. Nicholson, general manager of the Chicago, Milwaukee & St. Paul Ry. The new president is J. S. Robinson, division engineer, Chicago & Northwestern Ry.; C. A. Lichty, Chicago & Northwestern Ry., Chicago, was re-elected secretary.

St. Louis' Legal Right to Build Auditorium Upheld

A taxpayer's injunction suit to prevent the City of St. Louis from issuing \$5,000,000 of bonds for a municipal auditorium has been dismissed by a circuit court judge on demurrer by the city attorney. The judge holds that general powers of the city under its charter are broad enough to enable it to issue the bonds. He also states that courts of appeal have been almost unanimous in upholding the rights of cities to build municipal auditoriums.

Another Chicago Subway Plan

Of the many projects for subways in Chicago the latest is a simple one to relieve the extreme congestion of street traffic in the business district by removing from the surface the cars that come in from the west, southwest and northwest sections of the city. Since some of these car lines already use the tunnels under the Chicago River at Van Buren St., Washington St. and La Salle St., it is proposed to connect the first two tunnels by a U-shaped subway having its loop under Grant Park, at the lake front, and having a branch to the La Salle St. tunnel. This plan, suggested by R. F. Kelker, consulting engineer, could be extended later.

Pontoon Bridge Not Suitable

Washington Correspondence

Exceptions have been taken by the Secretary of War and the Chief of Engineers to published statements indicating that they allowed red tape to interfere with the relief of the situation caused by the burning of the North-End Bridge at Springfield, Mass. (See *Engineering News-Record*, Oct. 4, 1923, p. 540.) Their side of the matter is that Springfield interests did not want pontoon bridges after they were acquainted with the fact that the transportation cost on the nearest pontoons available would amount to \$53,000. They also had lost sight of the fact that a pontoon bridge is a one-way structure, and that two bridges would have been necessary. On being acquainted with these facts, the local interests decided that relief in that term was not desirable.

Agricultural Engineers Hold Chicago Meeting

Sectional meetings were the main feature of the annual convention of the American Society of Agricultural Engineers, held at Chicago on Nov. 8 to 10, the three general sessions being short and for the presentation of addresses. The farm structures section had papers on the structural design, ventilating and heating of farm buildings; also "Fire Resistive Construction for Timber Buildings," by T. F. Laist, National Lumber Manufacturers Association, and "Sewage Disposal Projects," by H. B. Walker, professor of agricultural engineering at Kansas State Agricultural College.

Tile drainage, soil erosion and land clearing were the principal subjects discussed by the reclamation section, the papers including "Drainage Investigations," by L. L. Hidinger of the Morgan Engineering Co., and "American Irrigation Since 1900," by Samuel Fortier, U. S. Department of Agriculture. Features of education in agricultural engineering constituted the program of the college section. Other groups of papers were considered by the farm power and machinery section and the rural electrification section.

Officers for 1924 are as follows: President, S. H. McCrory chief of division of agricultural engineering, U. S. Department of Agriculture; vice-presidents, L. J. Fletcher and E. R. Jones, professors of agricultural engineering at the University of California and University of Wisconsin, respectively; secretary and treasurer, Raymond Olney, Mount Clemens, Mich.

A Bolshevik Distinction

Lenin's argument was that Revolutionists must no longer be mere enthusiasts, idealists, and dilettantes; they must become professionals, "revolutionary engineers." . . . He wrote: "I trust that our champions will accept this technical word 'engineers' for when I speak of inadequate preparation I reproach myself. . . . The Revolutionists must not be degraded into the amateur."—From an article in *Die Neue Rundschau*, translated in *The Living Age*, entitled "Lenin, Revolutionary Engineer."

This should be a refreshing distinction to those controversialists who are not yet persuaded that engineering is a profession.

* * *

No Life of Ease

Sir—In this column of Oct. 18, 1923, I find "motion picture engineers" listed with the "moving engineers" and other pseudo-professional men. This is so manifestly unjust that I cannot let it pass. During the past year we have built short railroads where there was no excuse for a road, on the side of a wild gorge, taken a locomotive in (in pieces), set it up, and wrecked it in the same gorge. How would the average practising engineer like to get and how would he meet the following request: "Wanted—a practical set showing the side of an ocean liner, from water to top of stack; foreground to be water, with wave action, and liner to sink in same, tilting as it sinks to match stock film of sinking liner." Another request was for plans for a method of producing in "practical" earth, a suddenly appearing crack.

The art director wants a "visible" chart giving him the horizontal and vertical angles of all the lenses in use in the studio, so he will know the space required for his sets in advance, and his camera distances. The property man brings in a photograph of an existing dam and power house, and wants drawings of same, so he can build a scale model of it. He also wants to know the best method of arranging the construction of the model, so it can be blown up, and release an apparently large body of water. Add to all this the rejuvenation of old bridges, so as to be "practical," and their immediate re-aging so they will fall, and you will see that some engineering knowledge and ingenuity is required.

Those of your readers who imagine that we spend our time with peroxide blondes, and he-dolls with shellacked hair, are sadly mistaken, as badly mistaken as the misguided flappers who think motion pictures mean a life of ease. The hours are long, the work is often at high pressure to save the time of a large and expensive cast, and the engineers see little of actual production, except when their presence is required for engineering effects. "One of Them"

Highway Research Board Reviews Progress

Technical Committees Report—
Activities Hampered by
Lack of Funds

Engineering News-Record Staff Report

Co-ordination of highway research has made substantial progress in the last twelve months, as indicated by the reports of committees at the meeting of the Advisory Board on Highway Research of the National Research Council held in Washington, D. C., Nov. 8 and 9. About 60 research engineers and engineers interested in highway engineering and highway transport attended the three sessions and inspected the experimental work of the U. S. Bureau of Public Roads at Arlington, Va. Six committees on economic theory, structural design, road materials, finance, traffic and maintenance made formal reports and there were separate papers and sub-committee reports on rubber tires, mechanics of slabs, objectives of research, research by land grant colleges, research in North Carolina and motor vehicle performance.

The resignation of Prof. W. K. Hatt as director of the Board owing to his return to Purdue University was noted and the announcement made that E. R. Olbrich, construction engineer of the North Carolina Highway Commission, had been appointed technical assistant to the director. The appointment of a new director lies with the executive committee and will be made soon. Three bulletins have been published during the year. All work however has been hampered by lack of funds.

The by-laws of the Advisory Board provide for a committee on ways and means which has been appointed but has been inactive.

FUNDS LACKING

Shortly after the formation of the Advisory Board, Vice-Chairman Flinn planned to circularize a number of prospective contributors to the financial budget but the policy of the Board in respect to this matter was not settled. It appeared wise afterward to look to official sources such as state highway commissions and federal organizations for main support. While the Connecticut Highway Commission aided the Board with an appropriation for a period of two years, the desire of other commissions to take similar action was checked by legal barriers.

At the suggestion of the director contributions of money and equipment have been made by industries to research projects that were languishing and to which the Advisory Board was asked to give assistance. In such cases the funds are not handled by the Advisory Board. The only responsibility the director takes is in a matter of judgment as to the probable successful management of the research.

A field of work demanding direct expenditure of the funds of the Board is in holding conferences of research workers for the purpose of agreement on objectives of research and upon boundaries of fields of action. This fruitful service together with the expenses attending meetings of the research committees, can be extended if funds were available.

Wickenden to Administer Fund for Educational Study

William E. Wickenden, assistant vice-president of the American Telephone & Telegraph Co., has been chosen director of the committee which is charged with

administering the \$108,000 fund provided by the Carnegie Corp. for a "discriminating study of the present status of engineering education."

Award of the money to carry out research conceived by the Society for the Promotion of Engineering Education was noted in these columns last week. Mr. Wickenden is a native of Toledo, Ohio, and a scientific graduate of Denison University, which institution he left in 1904. After a year's teaching in Rochester he was a graduate student in physics and electrical engineering from 1905 to 1907 at the University of Wisconsin, later becoming an instructor in the same institution. In 1909 he was appointed assistant professor of electrical engineering at the Massachusetts Institute of Technology, being made associate professor in 1914. He remained at that institution until 1918.

In 1917 he made a study of educational and personnel problems for the engineering department of the Western Electric Co., research which led to the creation of a personnel department, of which he became manager in 1918. During that year he also served as regional supervisor of personnel methods for the Students' Army Training Corps. In 1921 he was transferred to the headquarters staff of the American Telephone & Telegraph Co. as assistant vice-president in charge of the recruiting and development of supervisory and technical personnel for the group of companies which comprise the Bell system. This work included the promotion of relations with universities and colleges throughout the country and supervision of the recruiting and introduction to the telephone business of approximately 2,500 graduates of engineering colleges.

Mr. Wickenden has written considerably for the technical press, his writings relating principally to illuminating and power plant engineering and to personnel problems in industry. He is chairman of the education committee of the American Institute of Electrical Engineers and chairman of the committee on relations with engineering colleges of the American Management Association. He was recently chairman of the committee on business training of the Society for the Promotion of Engineering Education.

Mr. Wickenden's home is in Upper Montclair, N. J.

The present income is only sufficient to pay the salary and traveling expenses of the director, and publication.

Following the reports from committees and special papers a technical summary of which will appear in the next issue the delegates re-elected A. N. Johnson as chairman and A. D. Flinn as vice-chairman of the Board for the coming year.

Railroads Make New Records; Plan Increased Efficiency

Peak Load Past—More Freight Handled
Than in Any Previous Period—
Program for Next Year

As a result of the ambitious plans made by the railroad companies last Spring to meet the demand for improvements in the transportation services, the greatest peak load season in their history has been passed successfully. The effort has resulted in setting up the following efficient records:

- (1) They have put into service 14,636 new freight cars and 2,963 locomotives, a larger number than in any similar period in the last decade;
- (2) a larger number of cars and locomotives have been repaired and put in serviceable condition than in any equal period. The percentage of locomotives in disrepair on Oct. 1 was the lowest in the history of the railroads;
- (3) more freight business was handled between Jan. 1 and Oct. 20 than in any corresponding period in history. The number of cars loaded with revenue freight in that period was 40,545,920, representing an increase of 10 per cent over the total for 1920, the previous record;
- (4) the average mileage a day attained by all the freight cars throughout the country in the first nine months was 27.6, and in September reached 29.2. This compares with 22.5 miles for the first nine months of 1922;
- (5) a record-breaking business was handled without congestion, and with practically no embargoes or car shortages;
- (6) the amount of freight service rendered with each car was 511 tons carried one mile daily, which surpasses the mark of a year ago by 31 per cent;
- (7) from Jan. 1 to Oct. 1, 23,268,635 tons of coal were dumped at Lake Erie ports for movement by boat to the Northwest;
- (8) a greater amount of railroad coal has been placed in stock-pile storage than was ever heretofore stored by the railroads.

ANNOUNCE A NEW PROGRAM

In order to continue the work of the past year and to make further improvements the American Railway Association has announced the following program for next year:

- (1) That there be a continuation of the intensive efforts of the railroads to reduce the percentage of locomotives and cars awaiting repair, and maintain it at the lowest possible minimum consistent with the volume of business offered and the revenues which the railroads are permitted to earn;
- (2) that there be increased supervision on the part of the railroads and greater co-operation with shippers to bring about better utilization of car capacity;
- (3) that there be continued the intensive effort to increase the average daily movement of freight per freight car and an endeavor to make new records of achievement in the prompt movement of traffic;
- (4) continued study and consideration of the possibility of the greater joint use of facilities;
- (5) that there be a continuation of the complete co-operation of the railroads in carrying out the directions of the car service division of the American Railway Association;
- (6) that active support be given by the railroads to all phases of the work of the regional shippers' advisory boards that have been organized by the public.

Engineering Societies

Calendar

Annual Meetings

FEDERATED AMERICAN ENGINEERING SOCIETIES, Washington, D. C.; Annual Meeting, Washington, D. C., Jan. 10-11, 1924.

AMERICAN ROADBUILDERS' ASSOCIATION, New York City; Annual Convention, Chicago, Jan. 14-18, 1924.

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York City; Annual Meeting, New York, Jan. 16-18, 1924.

ASSOCIATED GENERAL CONTRACTORS OF AMERICA, Washington, D. C.; Annual Meeting, Chicago, Ill., Jan. 21-24, 1924.

AMERICAN CONCRETE INSTITUTE, Detroit, Mich.; Annual Meeting (20th anniversary), Chicago, Ill., Feb. 25-28, 1924.

The California Section of the American Water Works Association held its fourth annual meeting at Fresno, Oct. 25-27, with an attendance of 150.

The Indiana Section of the American Society of Civil Engineers was recently organized, at Indianapolis. Presentation of the charter was made by John H. Dunlap, secretary of the American Society of Civil Engineers, who is making an organization tour of the Middle West and Pacific Coast states in the interest of the society. Mr. Dunlap gave an outline of the work of the national and state organizations. The meeting was attended by twenty members. Lawrence V. Sheridan is temporary chairman. Permanent officers will be elected at a later meeting.

Personal Notes

COL. THEODORE A. LEISEN, consulting engineer in charge of the construction of the 320-m.g.d. filtration plant at Detroit, Mich., has been made general manager of the Metropolitan Utilities District of Omaha, Neb., replacing R. B. Howell, who has resigned to take up his duties as United States Senator from Nebraska. Prior to his service in Detroit, Col. Leisen was chief engineer and superintendent of the water departments of Wilmington, Del., and Louisville, Ky., and consulting engineer of the water company of Frankfurt, Ky. In 1919 he was commissioned Major, Q.M.C., and had charge of the construction work at Camp Custer, Mich., later becoming lieutenant-colonel of the Reserve Corps. He is a past-president of the American Water Works Association. In Omaha he will take up the problem of the city's water supply.

E. R. OLBRICH, construction engineer, North Carolina State Highway Commission, has resigned to become assistant director of the Advisory Highway Research Board of the National Research Council with headquarters at Washington, D. C.

WALTER G. KIRKPATRICK, consulting engineer, Birmingham, Ala., has accepted a professorship of engineering in the University of Mississippi, of which he is an alumnus. Mr. Kirkpatrick was formerly city engineer of Birmingham, Ala., and had served in the same capacity in Jackson and Monroe, Ala. He was for a time special engineer for the Alabama Power Co.

MAXWELL V. SAUER has resigned as hydraulic engineer of design of the Hydro-Electric Power Commission of Ontario, Canada, to become hydraulic engineer of Canadian Vickers, Ltd., at Toronto, and consulting engineer to Vickers, Ltd., of England. After graduation from the engineering department of the University of Toronto, Mr. Sauer was with the Ontario Power Co. at Niagara Falls, as assistant to the mechanical engineer, then for a year he was chief designer for the Niagara Falls Power Co., Niagara Falls, N. Y., returning to the Ontario Power Co. as mechanical engineer. From 1913 for five years, as engineer of design for the Greater Winnipeg Water District, he was engaged in the construction of the Shoal Lake aqueduct and appurtenant structures, including a 100-mile railroad.

ALLISON H. BAER, who has been field secretary of the Associated General Contractors for a year, recently resigned to become secretary-treasurer for the Hitchcock-Tinkler Construction Co., which has been awarded the Moffat tunnel construction job at Denver. The new field secretary of the A. G. C. is WILFRED J. COLSON, who has been secretary of the Builders' Exchange of Worcester, Mass.

IVAN E. HOUK has resigned as city engineer of Dayton, Ohio, and has accepted a position as engineer with the U. S. Bureau of Reclamation. Mr. Houk will be stationed perhaps permanently in the Denver office and expects to be engaged on research work and hydraulic problems. He has had extensive experience in hydraulic investigation. In October, 1911 he became associated with the Morgan Engineering Co. of Memphis, Tenn., serving two years on hydraulic measurements and studies and the design of reclamation works and drainage structures in the lower Mississippi Valley. In 1913 he was made assistant engineer on flood prevention surveys and studies, being located at Dayton, Ohio, and was in charge of stream-flow measurements, investigations and hydraulic studies. Prior to his becoming city engineer of Dayton he was assistant engineer on Miami Conservancy District work.

LESLIE H. ALLEN has become associated with Russell B. Williamson, architect, Milwaukee, Wis., as partner and business manager. Mr. Allen has for the past two years been in charge of the Concrete House Division of the Portland Cement Association, and prior to that was for two years with Fred T. Ley & Co., New York, and for eleven years with Aberthaw Construction Co.

RALPH BEEBEE, city harbor engineer of Oakland, Calif., has resigned to accept the position of chief engineer with the Berkeley Waterfront Co., which plans extensive wharf improvements along the South Berkeley bay shore. HARRY HESS, assistant city harbor engineer, has been appointed to fill the vacancy temporarily.

PROF. VLADIMIR KARAPETOFF of the School of Electrical Engineering, Cornell University, has been awarded a prize of four thousand francs by the Montefiore Foundation of the University of Liege, Belgium, for his kinematic computing devices for representing complicated electrical relationships. In his experiments Prof. Karapetoff had the assistance of funds supplied to Cornell University by August Heckscher.

GEORGE J. CALDER, former resident engineer on construction of the filtration plant at Sacramento, Calif., and now construction engineer for the new Carquinez highway bridge across the straits, between Solano and Contra Costa Counties, has opened consulting offices at 1010 1/2 Eighth Street, Sacramento, Calif., with M. W. SAHLBERG, junior partner, in charge. Both are civil engineering graduates of the University of California.

Obituary

B. J. DALTON, who was chairman of the valuation committee of the Missouri-Kansas-Texas R.R. lines from 1916 to 1920, died at the Ka-y Hospital, Parsons, Kan., Oct. 28, aged 58 years. Mr. Dalton was a native of Franklin, Ky., and a graduate of the University of Kansas engineering school. For a time he was chief engineer of the Kansas, Oklahoma Central & Southwestern Ry. which was later absorbed by the Santa Fe system for which he became a resident engineer. Later he was chief engineer of the Denver, Elid & Gulf Ry. Previously he had served for two years as city engineer of Lawrence, Kan., and in 1906 he became professor of railway engineering at the University of Kansas. Prior to 1916 he was assistant district engineer of the Bureau of Valuation of the Interstate Commerce Commission.

COL. HENRY S. HAINES, retired railroad civil engineer and for many years connected with and at one time vice-president of the Plant System of railroads in the South, died at Lenox, Mass., Nov. 2, aged 86 years. Colonel Haines was born in Nantucket, Mass., educated in Savannah, Ga., and served in the Civil War as chief of transportation engineers. He advised the government of India on its change of railroad gage and was chief consulting engineer for the City of Paris on the increase of its water supply. He was the author of several standard works on American railroad management. He was a past president of the American Society of Civil Engineers and the American Society of Mechanical Engineers and of the American Railway Guild.

CHARLES M. CUNLIFF, superintendent of construction for the division of parks and recreation, St. Louis, Mo., died in that city Nov. 2, at the age of 32 years. Mr. Cunliff served in the engineering department of the Zoological Board of Control of St. Louis for four years, building the cliff bear pits in Forest Park and the Zoo Lakes. He served at the officers' training camp at Salt Lake City during the War, having enlisted in the 32nd Regiment of Railway Engineers.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Fitting the Electric Motor to the Pump

A Practical Discussion on the Application of Electric Drive to a Fundamental Operation in Industrial Plants

By R. H. ROGERS

Power and Mining Engineering Department,
General Electric Co., Schenectady, N. Y.

PUMPING is a fundamental operation in all industrial plants which lends itself admirably to electric drive. The selection of pumps, motors and control for the most successful operation is not a simple problem and if not well studied the plant is penalized continuously through the following years. The fact that some of the major industries with well organized engineering departments are operating many pumps with characteristics entirely unfitted for the service would indicate that this branch of engineering needs some explaining, especially for those who have little time for an intensive study of these problems.

The clearest way to show all the elements that affect the overall efficiency of electric pumping units is to analyze the whole span from the electric meter to the work accomplished, not overlooking other items that make an installation successful. The items that directly affect the kilowatt-hours per million gallon-feet are discussed below:

(1) *Ratio of Dynamic to Static Head.*—The vertical tape measurement from level to level or the calculated head, if pumping against boiler pressure, is not the measure of the pump's work. Every foot of pipe, every valve,

for sizes of pipes, valves and elbows at various velocities are available in pump catalogs and handbooks and they deserve close consideration.

In general, the piping should have much greater area than the pump openings, as high velocity is essential in the pump but detrimental in piping. From 6 to 8 ft. per second should not be exceeded; lesser velocities are desirable, for, once the system is installed,

FIG. 2—TYPICAL CURVES FOR 12-IN. CENTRIFUGAL AT CONSTANT SPEED

the loss goes on for years. The suction pipe especially should be deeply immersed, should be as short as is consistent with good installation practice and the bends, if any, should be of long radius. An excess of dynamic head over static head means just that much more work for the motor forever after, and if it is 10 per cent or 50 per cent that excess will show up at the meter.

Fig. 1 shows pump installations with no suction lift as they are placed alongside a sulphite stock tank. The piping is very liberal in size so that the difference between dynamic and static head is slight.

(2) *Pump Characteristics.*—Head, gallons per minute, efficiency, revolutions per minute and horsepower plotted together show the character of a centrifugal pump. If the speed at the point of best efficiency is at or near an induction-motor speed—1730, 1150, 865, 690 or 575 r.p.m.—it will insure its operation at the most efficient point if direct-connected to a squirrel-cage induction motor. If the horsepower required at the most efficient point is near one of the standard squirrel-cage motor ratings—200, 150, 125, 100, 75, 60, 50, 40, 30, or 25 hp.—it will insure a high overall efficiency for the set. Fortunately induction motors have a very flat efficiency curve through the working range, such as 90 per cent at full load; 90.5 per cent at 75 per cent load and 90 per cent at 50 per cent load, so that this feature has little effect. However, the power factors of such motors require that they be operated at near full load to keep the

current to a minimum. Power factor affects only the leads and generating system and not the meter, except as the rates may be adjusted to penalize low power factor in a plant. At loads as above, the power factor may be in the order of 89, 87 and 80 per cent.

A desirable characteristic in centrifugal pumps is that of having the load fall off each way from the best operating point. This prevents an overload coming on the motor by an accident or mishandling of valves which would subject it to maximum head (closed off) or minimum head (direct discharge).

Fig. 2 shows typical centrifugal pump curves for constant speed. The efficiency is high and fairly flat from 70 to 97 ft. head and from 4000 to 5600 g.p.m., hence the pump could be efficiently applied between these limits. The horsepower falls off both ways so that the motor cannot be overloaded.

(3) *Operating Off Rating.*—Pumps are rated naturally at their best operating point, and any deviation in speed, head or delivery will result in a higher cost per unit of duty. While some future conditions may have to be given consideration, operating at lower than rated head should be avoided, especially where a constant speed motor is used. Fig. 3 shows the variations in kilowatt-hours per million gallon-feet pumped by a 10-in. centrifugal direct-connected to the constant-speed motor which gives the highest overall efficiency at the pump rating. The gallon-feet pumped in a year at 135-ft. head for \$9,100 (2c. per kw.-hour) would cost \$17,000 if pumped at 45 ft. head with pumps of this class. This difference of \$7,900 per year is not out of line with many pumping duty costs that may be found among the misapplied pumps in industrial plants.

(4) *Choice of Motor.*—For constant-speed service induction motors of the squirrel-cage type or synchronous

FIG. 3—KILOWATT-HOURS REQUIRED FOR PUMP DRIVEN AT CONSTANT SPEED

motors may be used. Synchronous motors improve the power factor for the plant, and this may be enough to justify the valve manipulation incident to starting centrifugal pumps with such motors, together with the complication of bringing direct-current excitation to the motor. There is little difference in the efficiencies of the motors mentioned. For direct-current service the shunt-wound motor is not well adapted for centrifugal-pump drive as it is too sensitive to load and voltage changes. A compound-wound motor should be used with only a moderate series field, say 10 per cent; such motors have been standardized for centrifugal-pump service.

FIG. 1—LIBERAL SIZE OF PIPING REDUCES DYNAMIC HEAD

Sulphite stock centrifugal pumps (2,900 g.p.m., 66-ft. head) direct-connected to motors.

every elbow or other fitting adds to the theoretical to make the actual or dynamic head. For instance, considering only pipe diameter, a 5-in. three-stage centrifugal delivering 400 g.p.m. through 300 ft. of 5-in. pipe will cost \$375 per year more to operate than if a 10-in. pipe were used. This differential would pay for the larger pipe in a year. Tables of heads to be added

For adjustable-speed pump drives wound rotor motors, or the brush-shifting, commutator type of motors, may be used. The latter have much higher efficiencies at reduced speeds and this justifies their higher cost if operated at below normal speed frequently or for long periods. Fig. 4 shows the relative outlay in kw.-hours for an adjustable-speed pump using wound rotor and brush-shifting motors. The third curve shows the high cost of throttling to get reduced output. It will be noted that at 60 per cent of normal pump output the brush-shifting motor would operate 24 hours for \$10.72; the wound rotor motor for \$14.88; the squirrel-cage with throttled pump for \$25.20. The differences become greater upon reducing the output still more.

Vertical motors may often be used to great advantage by locating the pump at whatever depth may be necessary below the motor room floor. This reduces or eliminates the suction lift, with consequent benefit to the overall efficiency. Where grit is present in the water or the pump is inaccessible the entire weight of the revolving parts may be carried on a suspension thrust-

FIG. 4—RELATIVE OUTLAY FOR ADJUSTABLE-SPEED PUMP

compensators to which may be attached disconnecting switches and ammeters. The automatic compensators may be actuated by a push button at some convenient point, by a float switch, by a thermostat or by a diaphragm pressure switch.

Wound-rotor motors for constant-

Where it is desired to have the motor restart by itself after an undervoltage shut down, undervoltage release should be specified. Undervoltage release must also be provided if the motor is to be started by a float switch or other auxiliary circuit closing device.

The presence of explosive gases or of especially corrosive acid fumes necessitates the submergence of contact-making parts in oil. Such control items are available for all classes of pump service. For a battery of motor-driven gasoline pumps in a certain refinery the switches are of the oil-immersed type, and as a squirrel-cage motor has no moving contacts there is no danger of starting a fire or explosion.

Pump Service.—In conclusion, it is to be noted that motor-driven pumps are successfully coping with exacting classes of service in industrial plants. Liquids, whether thick, light, volatile or acid, are all being handled under manual or automatic control with the greatest facility. The flexibility of electric drive allows the plant engineer to draw a straight line from level to level, put the pump in the line practically without bends, with the assur-

FIG. 5—RECIPROCATING PUMPS REQUIRE HIGH STARTING TORQUE OF WOUND ROTOR MOTORS

FIG. 6—COMPOUND WOUND MOTORS WITH DISCONNECTING SWITCHES AND HAND STARTERS

bearing at the top of the vertical motor. This allows of easy inspection and maintenance. Vertical motors are available in synchronous, squirrel-cage, wound rotor, brush-shifting and direct-current construction.

Squirrel-cage motors can be used on centrifugal pumps up to 500 hp, provided the inrush of starting current is not objectionable. Wound-rotor motors start with much less line disturbance and are used for that reason even when intended for constant speed duty. Synchronous motors are not usually installed below 75 hp. and are, of course, for constant-speed duty only.

Reciprocating pumps, rotary pumps and screw pumps have heavy starting duty due to highbreakaway torque and full-load pumping duty from start. For these reasons squirrel-cage motors cannot be used if line disturbance is objectionable. Synchronous motors can be used, but the pump must be relieved of its load in starting so that the motor can pull into step. Wound-rotor motors for alternating current and compound-wound motors for direct current are best for pumps of this class, as they are possessed of strong starting characteristics. The brush-shifting commutator type of alternating current motor is equally good where adjustable speed operation is desired.

Pump Control.—Squirrel-cage motors are controlled by manual or automatic

speed duty may be controlled by an automatic panel actuated by push button or by float switch. The heavy starting duty on the reciprocating pumps determines the type of motors used.

Where adjustable speed is required or it is desired to control the starting by hand, a manual rheostat is provided in the secondary circuit while the line contact is made by a manual or magnetic switch. Synchronous motors are commonly controlled by a compensator and a field discharge switch.

Brush-shifting motors require only some form of line switch with overload protection and a mechanical means for shifting the brushes. This may be a hand-wheel, a shipper rod or a small pilot motor actuated by remote push buttons.

Compound-wound, direct-current motors for centrifugal pumps require a disconnecting switch and a hand starter. If adjustable speed is required a manual field regulating rheostat is added.

Direct-current motors may also be controlled by magnetic panels actuated by push button or float switch as in the case of the alternating-current motors. Fig. 6 shows compound-wound motors in a nitrate plant controlled by fused disconnecting switches and hand starters all neatly arranged.

Control apparatus in all cases should be fully enclosed and provided with overload and undervoltage protection.

ance that he can bring the power to the pump without any loss in efficiency or inconvenience to the plant.

American Lumber Commission Sails to Study Japan's Needs

An American commission of lumber exporters sailed from San Francisco Nov. 10 on the Japanese steamship *Taiyo Maru* to study Japan's lumber requirements for reconstruction in the area devastated by the earthquake. The American commission will conduct its survey and negotiations on behalf of more than 100 large export lumber mills in the Pacific Coast region. The commission is composed of Major E. G. Griggs, of Tacoma, Wash., president of the Douglas Fir Exploitation and Export Co.; O. M. Clark, of Portland, Ore., lumber manufacturer, and Chester J. Hogue, of Seattle, manager of the West Coast Forest Products Bureau.

This group of lumber authorities will visit Tokyo, Yokohama and other Japanese cities and confer with Japanese commercial interests identified with plans to furnish emergency supplies of lumber in large volume, and with the least delay possible, to meet rebuilding needs. A special effort will be made by the commission to induce Japanese lumber buyers to accept shipments of American standard lumber sizes.

To Investigate "Dumping" of Foreign Cement

Foreign representatives of the Customs Special Agency Section of the Treasury Department have been instructed to investigate and report as soon as practicable the foreign market values back to April 1 of British, Norwegian, Swedish, Danish and German cement and to forward any other information available bearing on the question of "dumping."

This inquiry results from complaints by the Sun Portland Cement Co. and the Oregon Portland Cement Co. to the collector of customs at Portland, Ore., that cement was being imported from Norway and Sweden at prices below the home market price, thus coming into conflict with the anti-dumping act of 1921.

Tokyo Organizes Huge Building Company for Reconstruction

A huge building construction company is being organized in Tokyo for the purpose of undertaking the construction of commercial and industrial buildings on the unit basis, says a report received by the Far Eastern Division of the Department of Commerce from its representative at Tokyo. This company plans to specialize in four-story reinforced concrete buildings designed to withstand earthquake shocks. Such material as cannot be obtained locally or which cannot be supplied in standard specifications, it is announced, will be obtained abroad.

Funds for the promotion of this new company will, according to present plans, be obtained in large part from the Government at a low interest rate. At present the company is marking time awaiting the announcement of the plans of the Capital Restoration Board as to the areas set aside for industrial and business purposes.

It appears at present, says the Department of Commerce, that in addition to securing abroad a large part of the iron and steel and lumber that goes into the permanent reconstruction, considerable quantities of cement will have to be imported as well. Ordinarily Japan exports considerable cement but the enormous demand that is bound to come with the commencement of permanent building activities, coupled with the destruction of about 8 per cent of Japan's cement production, will be greater than the industry can meet.

The annual capacity of Japan's cement mills was, before the earthquake, in the neighborhood of 14,000,000 bbl. and plans are under way which will, within six months' time, bring this up to 17,000,000 bbl., notwithstanding the losses suffered by the earthquake. Until such time as this increased output is brought about it is expected that the domestic supply will be inadequate and that considerable cement will have to be imported. In anticipation of this need, the Government has placed cement on the free list effective until March 31, 1924.

Conservative bankers in Tokyo are advocating a program of reconstruction spread over a period of 20 years and financed in most part through the flotation of domestic loans. In order to keep the yen on an even keel, however, they favor the flotation of foreign loans sufficient to cover all purchases made abroad.

Business Notes

ORTON & STEINBRENNER Co., 608 So. Dearborn St., Chicago, manufacturer of locomotive cranes and buckets, has just completed a large addition to its works at Huntington, Ind., which will double the output of the company. All equipment for the addition to the plant, including a large number of modern machine tools, has been purchased and most of it is already in use.

H. B. ACKLAND has been appointed manager of the New York office of the G. H. Williams Co., Erie, Pa., manufacturer of clamshell buckets. Mr. Ackland is a mechanical engineer and was formerly with Westinghouse, Church, Kerr & Co.

C. H. LOOMIS & SONS Co., equipment distributors, Newark, N. J., announces the occupation of a new warehouse at 304-306 Jelliff Ave., housing a line of contractor's plant which includes Rex concrete mixers, Domestic gasoline engines, pumps, hoists and air compressors, and American portable sawmill rigs.

Equipment and Materials

Hoist Attachment for Tractor

A hoist attachment that can be fitted to a Fordson tractor in 15 min. has been added to the line of construction equipment manufactured by the Clyde Iron Works, Duluth, Minn. It consists of a friction-driven drum 8 in.

in diameter, 10 in. long between flanges and with 18 in. diameter flanges supported in a cast-steel frame. It is fastened to the tractor by eight of the rear axle housing bolts and two bolts through the outside holes of the draw-bar cap. The frame is designed so that no drilling, tapping or machine work of any kind is required to attach it to the tractor and the hoist is mounted so as not to interfere with the tractor in any of its uses.

The drum is equipped with the Clyde standard wood cone frictions and thrust mechanism, bronze bushings with grease cup lubrication, a hand-brake that is asbestos-lined and operated by a foot lever and also ratchet with pawl. All shaft bearings are babbitted and lubricated with grease cups, the drum shaft bearings being equipped with removable caps. Power is received through a roller chain from the pulley shaft, the pulley being replaced with a sprocket. A rod on the lever side of the drum gives the operator full control of the throttle.

The hoisting duty of the attachment is 3,900 lb. at 142 ft. per minute for the first layer of $\frac{1}{2}$ -in. cable and 2,320 lb. at 242 ft. per minute when the last or seventh layer is on the drum. The hoists are mounted on timber skids for shipment and weigh 600 lb. each, including the tool box.

Floating Roof for Gasoline Tanks

Fire tests were conducted Oct. 16 at the Chicago plant of the Chicago Bridge & Iron Works to prove the ability of the Wiggins floating welded-steel roof to protect the contents of

oil and gasoline tanks. This roof, built for experimental purposes, floated on the surface of gasoline contained in a steel tank 6 ft. high and 30 ft. in diameter. The tank contained about 3 ft. of water on top of which there was an average depth of gasoline of $2\frac{1}{2}$ to 3 in. There is a gas-tight space (see drawing) between the vertical rim of the floating roof and the shoe which presses against the tank shell; this small air space is the only one between the surface of the liquid and the roof. Evaporation is prevented by a special form of seal shown in the accompanying drawing.

In the tests fire applied at numerous points and in different ways failed to start any permanent conflagration. The results, it is claimed, demonstrate not only the fire prevention features of the floating roof but also its value in eliminating evaporation losses.

Publications from the Construction Industry

Metal Lath—ASSOCIATED METAL LATH MANUFACTURERS, Chicago, has published in the form of a 16-p. pamphlet approved specifications for metal lath construction. The specifications cover the quality of material and methods of application of all types. For years manufacturers of metal lath have given out slightly conflicting recommendations on the use of their products. The present set of specifications aims to present, in so far as it is possible to do so, uniform recommendations. In addition to the text, there are a number of drawings showing the use of metal lath in a variety of building construction details, including partitions, ceilings, floors and cornices.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Steel Ingot Output Gains—Slight Drop in Pig Iron

The October steel ingot output showed a gain of nearly 7 per cent, compared with the month preceding, according to the American Iron and Steel Institute. There were 3,382,986 tons produced last month, in the steel mills of the country which turned out 84.15 per cent of the steel ingot output in 1922. The September total was 3,161,964 tons and that for October, 1922, 2,872,415 tons. Production figures, for the first ten months of the current year, are compared with 1922 in the following table:

Months	Tons of Steel Ingots 1923	1922
January	3,466,629	1,593,482
Feb.	3,294,264	1,745,022
March	3,858,675	2,370,751
April	3,760,997	2,444,513
May	4,000,695	2,711,141
June	3,374,567	2,634,477
July	3,350,829	2,487,104
August	3,506,755	2,214,582
September	3,161,964	2,373,779
October	3,382,986	2,872,415
November		2,889,297
December		2,779,890
Total	35,536,361	29,116,453

The October pig-iron output, however, showed a slight drop from the month preceding. Over 3,149,000 tons were produced last month as against 3,125,000 during September. Compared with the May production peak, the October output dropped 18½ per cent, making it the lowest rate for any month in the current year.

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for, in Construction News, pp. 265 to 277, are the following:

Hotel, Durham, N. C., Citizens Hotel Co., \$1,000,000.
School, New York, N. Y., Supt. Bd. of Educ., \$1,500,000.
Hotel, Ashland, Ky., Buckingham Hotel Co., \$1,000,000.
School, Brooklyn, N. Y., Supt. Bd. of Educ., \$1,500,000.
Hotel, Paterson, N. J., Alexander Hamilton Hotel, \$1,000,000.
Hotel, Duluth, Minn., W. Schroeder, \$1,500,000.
High School, St. Louis, Mo., Bd. of Educ., \$1,500,000.
Apartment, Philadelphia, Pa., C. E. Oelschlager, \$1,500,000.
Hotel, Tacoma, Wash., Citizens Hotel Corp., \$1,500,000.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 265 to 277, are the following: Filter and Admin. Bldg., Cleveland, Ohio, to Stange-Walsh Constr. Co., \$2,885,500.

Bank and Office, Cleveland, Ohio, to Fuller Constr. Co., New York City, \$5,000,000.

School, Brooklyn, N. Y., Bd. of Educ., to C. Colon and Co., \$1,030,000.

Hotel, Long Beach, Calif., to Hennessy Bros., Los Angeles, \$1,250,000.

Public Bond Sales Active

The month of October shows greater activity in the bond market than the three preceding months. *The Commercial and Financial Chronicle* reports the total of state and municipal bonds placed at \$81,940,676, the highest since June. September of this year placed \$51,860,828 and October, 1922, \$71,333,536.

The largest issue during October was the \$21,000,000 block of Illinois bonds. West Virginia negotiated a sale of \$2,000,000 4½s which is a part of a \$5,000,000 offering. New York bankers took option on the remainder of the bonds.

Bonds offered but not sold for October totaled \$31,000,000.

The total of all the various forms of loans placed in October for the past five years follows:

1919	\$108,519,268
1920	170,791,051
1921	189,847,801
1922	163,258,214
1923	347,998,755

In the accompanying table of representative bonds, six were sold at par, four below par, and the remainder above. The yields ranged from 4.201 to 6 and the rate of interest from 4 to 6 per cent.

Next week—"Water-Works Installation in 1922 and 1923"

Ten Largest 1923 Contracts Total \$85,328,722

From contracts awarded published in *Engineering News-Record*, the ten largest to date are given in an accompanying table. Three of these are in New York City with a total of \$23,226,086, while Chicago with three, totals \$21,602,636. The remaining contracts are not located in commercial centers. It is also noteworthy that on the whole, contracts were awarded to contractors located in the centers where the construction was done. Also out of the nine classifications into which the types

of construction are divided in Construction News, six of them are represented in this list. The largest was for a \$20,000,000 power plant in New Jersey.

TEN LARGEST CONTRACTS—JAN. 1 TO NOV. 1, 1923					Successful Contractor	
Date	Work	Location	Price			
Feb. 1	Office	New York City	\$6,000,000		I. T. Ley & Co., New York City	
Feb. 8	Office	Chicago	8,000,000		Starratt Bros., Chicago	
Apr. 5	R. R. & telegraph system	Montana	12,000,000		Peterson-Shirley & Guntler, Omaha, Nebraska	
June 7	Subway	New York City	5,976,086		Patrick McGovern, New York City	
June 28	Telephone exchange	New York City	11,250,000		Mare Edlitz & Son, Inc., New York City	
July 12	Office	Chicago	8,000,000		Wells Bros. Constr. Co., Chicago	
Aug. 16	Sewage works	Chicago	5,602,636		J. Griffiths & Sons Co., Chicago	
Sept. 6	Dam	Dunville, Ky.	4,000,000		L. E. Meyer, Chicago	
Sept. 13	Bridge	California	4,500,000		Duncan-Harrelson, San Francisco	
Oct. 18	Power plant	Kentucky, N. J.	20,000,000		Pub. Service Prod. Corp., Newark, N. J.	
Total			\$85,328,722			

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted. Valuable suggestions on costs of work can be had by noting actual biddings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Nov. 1; the next, on Dec. 6.

Explanation of Prices—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or - signs. For steel pipe, the prevailing discount from list price is given; 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b. Labor—Concrete laborers' rate, 93c.; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. The price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu. yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5 $\frac{1}{2}$ x 8 x 11 $\frac{1}{2}$. Prices are all f.o.b. warehouses except C. I. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir, common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on pine lumber. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick, f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 98.23). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$47.43; 6-in., \$119.

Changes Since Last Week

Recent price reductions in basic building materials have resulted partly from seasonal influences and partly from plentiful supplies. These concessions have resulted in an unusually large winter building program in all classes of construction. Federal Government projects especially, having been held up for some time, will enter the market at a time when competition for labor and materials is not so keen.

While the construction outlook is well-defined, the same cannot be said

of business generally. The stock market has improved recently; money is fairly easy; freight loadings are unseasonably heavy; the recent steel dividend indicates an optimistic outlook in that industry, yet foreign exchange rates have dropped still further; curtailment has occurred in the pig-iron, textile and leather output and freight rate reductions on grain and coal remain unsettled. Shipments of locomotives from the principal manufacturing establishments to the various

railroads, during the first ten months of the current year, increased 183 per cent over the same period in 1922.

The declines referred to have occurred mostly in concreting materials, lumber and clay products, and have not affected such items as steel, lime and labor costs. Linseed oil, however, has steadily declined carrying with it paint prices in general. Other raw materials entering into the manufacture of paint have not declined in proportion.

Number 21

Paying for the Coal Reserves

PART of the mounting cost of anthracite coal is made up of interest on the ever-increasing capitalized value of the coal lands held in reserve for future use, according to the latest report of the Coal Commission. This has got to stop sometime if the price of coal is to be kept within reasonable bounds. As the supply of coal is depleted the value of the remaining coal lands will increase and if the owners of these lands are to be allowed to keep on increasing the capitalized value of these lands the interest on this capitalized value which now makes up part of the cost of the coal being mined will increase correspondingly until the cost of coal becomes prohibitive. Just how such coal lands are to be valued is not an easy question to answer for to hold exactly to the original cost value would work an injustice to the coal companies who bought their lands years ago for little or nothing but who held them through the losses of pioneer days. Yet there is still greater injustice in the method of enhancing values such as was used when the stockholders of the Delaware, Lackawanna and Western R. R., when separating the railroad from the coal business, sold their coal properties, valued at \$6,240,000, to themselves as stockholders in the Alden Coal Co. for \$72,240,000. We can think of no better way to hasten nationalization than a few more such exhibitions of capitalizing monopoly property possession.

Valuing Monopolies

THIS whole matter of capitalizing the unearned increment due to monopoly control is in for serious consideration in the next generation. One does not need to have radical or "red" tendencies to see the difference between profiting in the rising value in land in a city or in a wheat growing country and the same kind of profiting in coal lands, or possibly as time goes on in oil lands and even water power. There is nothing that compels people for all time to do business near the corner of Broad and Wall St. in New York. When rents become prohibitive there the prospective lessee moves elsewhere where the leasing cost is low enough to enable him to operate at a profit. Coal, on the contrary, is a disappearing necessity and the undisputed possessor of as much of it as remained would in time have the rest of the country in his complete power. Obviously nothing like that is going to be permitted but the difficulty is going to lie in determining where monopoly ownership shall be permitted to stop. There is a sufficient analogy in the matter of water power to give all power people pause. Is it possible that some of the public resentment against private power interests is due to the fear that as water power becomes more and more a necessity the valuation of water rights will be correspondingly increased to a point where a fair return on such monopoly value becomes outrageous?

An Arbitration Court

ARBITRATION proceeds apace in the construction industry. The New York Building Congress has adapted an arbitration clause whose inclusion in all building contracts is advised and which has features not common in such contract provisions:

All disputes arising in connection with this contract shall be submitted to and determined by arbitration, as provided in the arbitration law of the state of New York, in a Tribunal of Justice to be known as the Court of Arbitration of the New York Building Congress, to be established and conducted by the New York Building Congress (Arbitration Committee), under the rules of procedure as set down by the Arbitration Society of America as of Sept. 1, 1923.

It will be observed that provision of the machinery for conducting arbitration cases is indicated. This consists of the selection by the Building Congress of half a hundred men competent to act as arbitrators and the services of its Arbitration Committee to arrange place and time of meeting and establish rules and methods of procedure in conformity with the arbitration law of New York. In brief a Court of Arbitration is established. This is constructive action well in advance of most of similar contract arbitration plans.

Floods and Waterway Transportation

COLONEL ASHBURN'S report on the government's Mississippi River freight service, noted in the news pages, is an excellent defence of the waterway as a freight carrier but it contains, inadvertently perhaps, the best possible explanation of the continuing disability of the Mississippi to compete with its paralleling railways. During the spring and summer of 1922 the great river was in flood, so that for a month or more navigation was dangerous and freight landing on nearly overtopped levees impossible, while for a succeeding half year the channel, twisted and shifted by the record flow, was either unmarked or impassable. In consequence tonnage carried, which had been approaching a paying basis, fell so low that only an enormous surplus or the resources of the government could have saved any shipping line from bankruptcy. The director of the service rather intimates that this could have been avoided had proper engineering control of the channel been exercised and accepts the disaster of 1922 as something which could be avoided in the future. This is a doubtful attitude. The Mississippi will continue to have floods, so long as rain continues to fall in the valley, and those floods will continue to warp and wreck an already tortuous channel. No engineering control within the bounds of financial possibility can prevent it. Any operation of freight service on the river, therefore, must count on recurring periods of long disuse, or at best difficult use, with loss of profit during those periods, as well as the loss of favor which a discontinuous service entails. And this is a heavy impost for any commercial enterprise to carry.

Art and Craftsmanship

VERY recently someone remarked in a discussion of highway bridge specifications before the American Society of Civil Engineers how noteworthy it is that three separate "standards" for such specifications should be simultaneously under consideration. Not only the society but also the American Railway Engineering Association and the Association of State Highway Officials have drafted such standards, each intended to become established as the universal rule of good bridge building. For many years we have had specifications, expressing the preferred practice of this or that engineer, but present specifications are the direct antithesis of the old ones, since they represent not an expression of individual engineering judgment but its elimination in favor of unvarying uniform practice. The spirit of the past was to make bridge practice good by enlisting the best and freest engineering judgment; the new spirit is to prevent the exercise of such judgment and if feasible enforce uniformity for the sake of good bridges. The situation is indeed significant. Let the reader picture to himself an attempt to draw up standards for arch dams, or for sewage disposal tanks, or for harbors, anything that is recognized as a subject of true engineering activity. Such an attempt is an evident impossibility; any standard for even temporary use would be a statement of the problem only, not of the method or nature of its engineering solution. Were it possible to write standard rules for the engineering solution, it would mean that the subject in question had become so routinized as to be removed from the field of engineering and be relegated to the domain of craftsmanship. Thorough training in calculation may be required to lay out rivets under an algebraic rule of spacing, yet the process will still be craftsman routine. The deciding issue is whether scope is left for the exercise of judgment and ingenuity in meeting the demands of the service which the structure is to meet. If upon answering this question it is found that steel highway bridge construction has indeed passed out of the realm of the engineer into that of the artisan, then the engineering profession has reached the close of the book in one line of its great endeavor of making the teachings of science subservient to the needs of a practical art.

Highway Bridge Troubles

REFERENCE to the experience records of highway bridges for the past year or two brings out a point that bears somewhat on the question of design rules, discussed just above. Very few accidents have been reported which could be charged to bad proportioning or detailing of the steel construction. On the other hand, many accidents are found to have been caused by conditions unrelated to steel practice. Speaking in approximate terms, once a week a bridge has been reported wrecked by a colliding vehicle which struck the end posts, or pushed the structure off its seat, or tore out a web member. Once a month—again approximately—a failure resulted from a bridge being too narrow for safe passage of vehicles or being so located with respect to the approaches that entrance of vehicles was unduly difficult (and therefore in the long run hazardous). It would seem that in so far as it is the bridge engineer's business to build safe bridges, he has primary concern with matters that lie beyond rivet spacing or permissible width of cover plates. Sound principles of highway bridge construction undoubtedly

include among other things certain principles of safe location, layout, and guarding. However, it is not customary to treat of these matters in bridge specifications, and they are not included in the three standards which are now being discussed. Perhaps such specifications are not meant to be guides to good bridge construction. If so, some misconceptions would be avoided by labeling them accordingly; every one should be permitted to know, as bridge engineers know, that not every bridge meeting the standard specifications is a good bridge, and that good bridges may be built which do not satisfy the specifications. If the limited character of the current standard specifications were clearly noted, it might have the result that good bridge construction in its broadest aspects would find a place in technical discussion.

Lessons from Paris Refuse Disposal

WHEN the private company which disposes of the mixed garbage and other refuse of the city of Paris completes its improvements and extensions to its disposal plants, Paris will have what promises to be the most complete system of refuse collection and disposal of any large city in the world.

Under this plan, which is outlined at length elsewhere in this issue by the technical director or managing engineer for the disposal company, the mixed refuse is collected by hundreds of motor trucks, owned by private companies and driven by chauffeurs provided by the company but directed and loaded by the city. These trucks deliver the refuse to four disposal plants where, by means of sorting, screening and grinding, all the material of commercial value is reclaimed for utilization. The residue goes to furnaces which yield still further by-products—heat, which is converted into steam and thence into electric current, and clinker, which is made into brick. The city seems to exercise such a complete control of refuse collection as will enable it to insure good service, while the disposal contract seems on the one hand to guarantee a fair profit to the contractor and on the other to be well designed to give the city a share in any excess over fair profit.

All the data at hand indicate that the Paris plan is worthy of careful study by cities and by engineers concerned with garbage and refuse disposal, in whatever country located. By this we do not mean to advocate mixed as against separate collection and disposal of city wastes, nor sorting, screening, and incineration against any other method of final disposal, nor, least of all, do we mean to advocate private rather than public agencies for collection and disposal of municipal refuse. What we do urge is the same careful attention by other municipalities as seems to have been given by Paris to working out a system of refuse collection and disposal adapted to local conditions, which, if private agencies are employed, will protect them against undue risk, while at the same time giving the city some share in the profits, if any, from utilizing municipal wastes, all to the end that the net combined cost of refuse collection and disposal, which is bound to be considerable in any case, may be cut to the lowest figure compatible with good service.

Paris affords a notable example of the change in the incineration of mixed refuse that has been going on abroad of late—in part led by Paris. In that city and in a rapidly growing number of British towns, the entire collection of mixed refuse does not go to the

incinerator. Instead, all material of commercial value is salvaged; paper, etc., for sale, garbage and fine ash to go to land for its fertilizer value and for the physical improvement of the soil. In particular, it is to be noted that by eliminating ashes and as much as may be of other incombustible waste, the calorific value, pound for pound, of what goes to the furnaces is greatly increased, while the furnace output, for re-handling and final disposal, is not only much decreased, but what does remain is almost wholly a clinker—useful abroad, whether or not it would be in America, for making brick or concrete. It should be noted also that all this applies to mixed refuse only and not to furnaces for burning garbage alone or garbage mixed chiefly with paper, tin cans, bottles and the like, as is the case in so many American municipalities that have attempted incineration.

In conclusion, it is well to remember that although a considerable number of American cities have installed equipment to utilize the heat generated by burning city refuse, but rarely has any of the heat generated been used except at the disposal plant, if even there. Under existing conditions, there seems, if anything, less chance of heat utilization in this country than there has been in the past. This makes all the more interesting and important the results that may be achieved at Paris when the enlarged plant and new scheme are in complete operation. It is hoped that careful records will be kept and will be made available.

A "Business Administration"

BUSINESS principles are to govern the administration of federal reclamation henceforth, said the Secretary of the Interior as he discharged Arthur P. Davis. No more engineers, but business men instead, and the business type of management! Accounts have just come from the far West that detail the first item of this improved management, as carried out in this instance by the Secretary himself—the "business man" upon whom the country is compelled to depend at the moment for the guardianship of our national investment in reclamation projects.

Each of the score or more reclamation projects is a large-scale business undertaking, in which an investment of many millions of dollars must be cared for and an annual business of four or five million dollars administered. The machine by which such a business is handled is of necessity a carefully organized mechanism, as certain to be damaged by unskilled tinkering as a watch. Yet the Secretary has ordered the summary disruption of one of these operating mechanisms, on no better basis than the wanton and ignorant recommendations of an "inspector" qualified for the examination of reclamation projects by a long career as a political henchman. What is more, the Secretary in issuing this order went over the heads of the two officials who are in direct charge of the management of projects and answerable for their proper organization and sound management.

Somewhat more in detail. Since early summer the way has been prepared for improved reclamation management by visits of several sets of inspectors to the projects. The merit of certain of these inspectors consisted in their having no knowledge of reclamation but an intimate knowledge of politics. One of them, a hanger-on of New Mexico party politics and appointed to a position in the Interior Department by A. B. Fall

of that state when he was secretary, more especially engaged the confidence of Secretary Work. The activities of this "inspector" while on his visit to the projects seem to have consisted largely in stirring up trouble among the farmers. It may as a matter of charity be assumed that the Secretary has not been advised of the proceedings of this inspector on the projects, but his procedure in blindly adopting the mischievous and destructive recommendations of the inspector can hardly be covered with the same mantle of charity.

Reports which we have obtained of the inspector's doings at the Newlands project, in Nevada, join in showing the following. He collected groups of malcontent farmers and townsmen in Fallon, the chief city of the project, invited complaints, and promised, on the part of the Secretary, any concessions that might be asked for. Specifically in response to some of the complaints he promised that various persons would be paid for canal rights-of-way, unconcerned about the fact that this subject had already been covered by agreements and deeds arranged for by the project organization. He further induced the malcontent water users to appoint a committee to draw up complaints, and led them to prepare silly resolutions condemning "the unjust and discriminatory freight rates paid by the settlers" and holding "the Reclamation Service with their vast influence criminally negligent in permitting this injustice." After engaging in a fight with the Reclamation Service's gate tender at Lake Tahoe (a local paper says, while the inspector was drunk) he reported that this man should be dismissed and that half a dozen other dismissals and shifts should be made in the operating staff of the project. Innocent of experience in project operation, he decided upon recommending the disruption of the project organization built up by the project manager, a man of exceptional ability and long experience in this difficult and responsible work.

Secretary Work's action on this report was to adopt the inspector's recommendations in bulk, over the heads of both the reclamation commissioner and the chief engineer. Under date of Aug. 23, Secretary Work, by letter, directed Commissioner D. W. Davis to have carried out at once the recommendations of the inspector as follows:

- (1) To discharge the purchasing agent, his work to be performed by the chief clerk, "who should have the stenographer write his letters; or, when everybody else is busy, should type his own orders, etc."; (2) to use a neostyle in making up forms and papers, (a duplicating machine was already in use in the project office); (3) to discharge the office engineer, his work to be divided between the project manager and several of the field engineers; (4) to designate the chief clerk as acting project manager in the absence of the project manager; (5) to discharge the gate tender at Lake Tahoe, and endeavor to secure a local resident to perform his duties, "the position to be filled by a man whose comportment and behavior will avoid criticism of the department"; (6) to discharge the water master, and have the superintendent of irrigation perform his duties; (7) to discharge the master mechanic, and have the engineer of drainage perform his duties.

Neglect and mishandling are sure to result from disrupted organization and the destruction of morale resulting from this type of "business" management. Whoever has the interests of the reclamation projects at heart will look with anxious hope to the assembling of a new Congress and to the possible awakening of the President to the activities of the spoiler who represents him at the head of the Interior Department.

City Forces Build Sewage Treatment Works

Remarkable Construction Plant Installed by Sewer Department of Worcester, Mass., for Force Account Construction of Imhoff Tanks and Trickling Filter

BY EARL R. PERRY

Superintendent of Construction, Worcester, Mass.

NOTABLE construction characterizes the new sewage treatment works at Worcester, Mass. One of the largest Imhoff-tank and trickling-filter installations of the world is being put through successfully by day labor. The operation is very nearly self-contained; all materials are produced on the job except cement, lumber and the metal elements of the structures. All major equipment, even the 32x40-in. jaw crusher, is electrically operated. Minor features are form erection practically without falsework, cement-gun fabrication of thin slope walls of sedimentation chambers and winter concreting of heavy walls.

Explanation of each of these outstanding features is more appropriately made elsewhere except in the case

comprise primarily Imhoff tanks, dosing tanks, trickling filter and secondary tanks. This location, however, necessitated, as indicated on the map, the extension, for about a mile, of the 72-in. outfall sewer. About 1,500 ft. of this extension is inverted siphon across swamp; the maximum head is 26 ft. and there are blowoff valves for drainage. The new sewer will have a capacity of 66 m.g.d. To increase the fall through the treatment units the channel of the river below the works was diverted as indicated on the map.

The structures on the sewer line are a Venturi meter and a grit chamber. The grit chamber, having two compartments with coarse bar screens, is located just above the point where the sewage will enter the siphon.

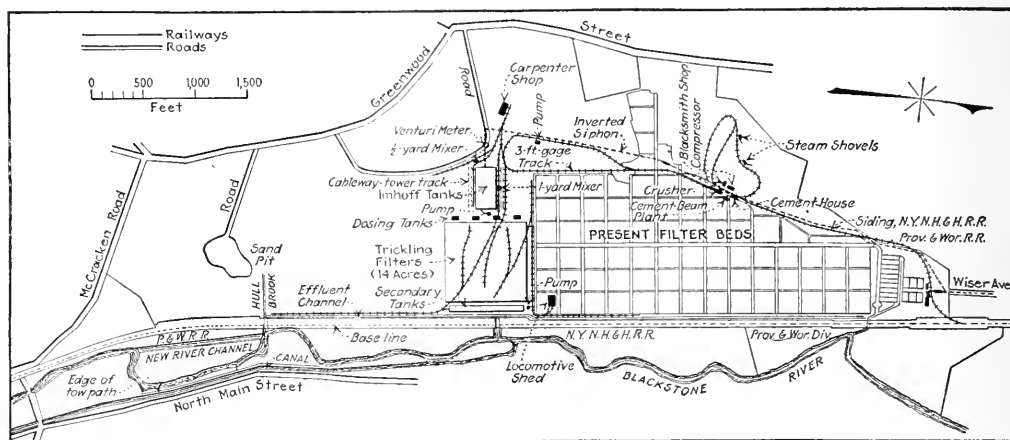

FIG. 1—CONSTRUCTION PLANT AND SERVICE RAILWAY LOCATION MAP

of force account work. This followed from the fact that the work was for Worcester. With the exception of buildings, the construction work of this city has always been done by its various departments. Therefore, when the treatment plant came to the point of construction the Sewer Department was instructed to undertake the work. With a portion of its personnel as a nucleus, a working organization of between 200 and 300 men was developed. Heading this organization are David M. Earle, city engineer; Ralph G. Lingley, superintendent, Sewer Department; and Earl R. Perry, superintendent of construction. Doing the work by day labor has been as rapid as and certainly no more expensive than contract construction. It is noted that only construction is considered in this article as follows: (1) structures, (2) plant, and (3) methods.

Structures—A map of the land owned by the city for sewage treatment purposes is shown by Fig. 1. Because its topography conformed fairly well to the requirements, the area just south of the present sewage filter beds was selected as the site of the new works which

It has sufficient cross-sectional area to reduce the velocity of the sewage from 3.8 ft. to 1 ft. a second. The two compartments will hold 100 cu.yd. of grit and will be cleaned by means of a clamshell bucket. As indicated by the map the 72x30-in. Venturi meter is located between the siphon and the Imhoff tanks.

In the Imhoff-tank unit there are two batteries of six tanks of the double type. The main influent and effluent channels separate the two sets of six tanks. One of the tanks is shown by Fig. 2, which indicates the general structure and the arrangement of the channels, which are all open and provided with gates for controlling and reversing the flow. The twelve tanks are designed to care for a daily flow of 28 m.g., or the sewage of an estimated population of 243,000 in 1934.

Each double tank, Fig. 2, is 61x90 ft. in plan and has a total depth of 33 ft. The tanks have a freeboard of 2 ft., a gas vent area of 21 per cent, and a detention period of 21 hours. There are four sedimentation chambers in each tank with slopes 1½ to 1 and a total capacity of 240,300 gal. or 32,040 cu.ft. The sludge

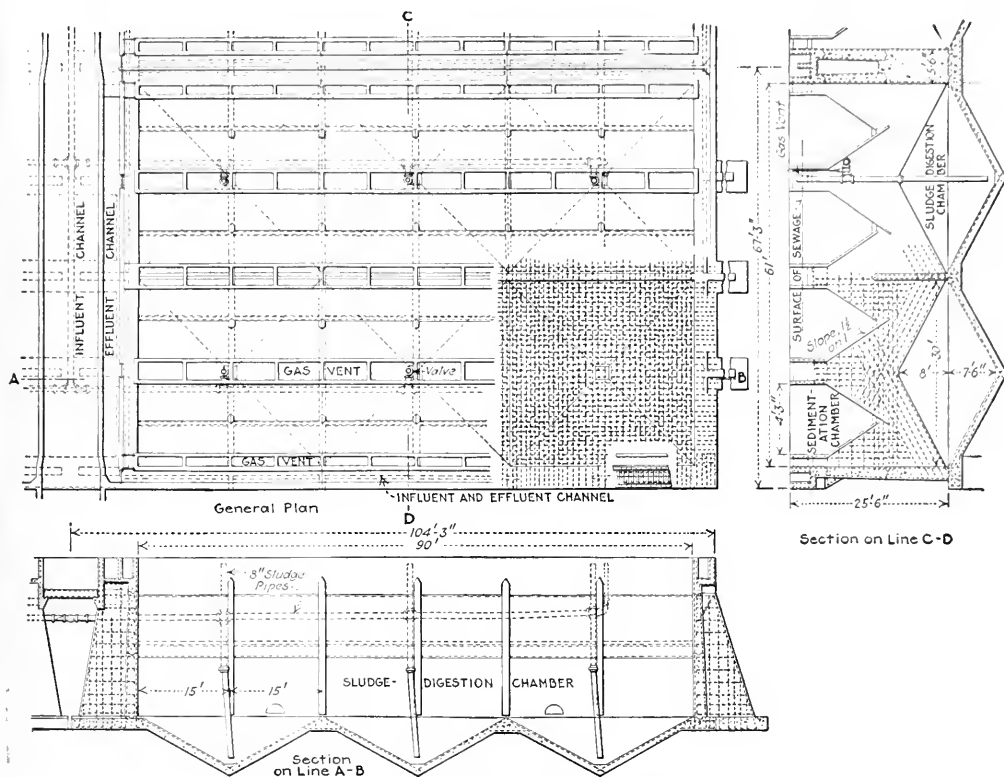

FIG. 2—DETAILS OF IMHOFF TANK—ONE OF TWELVE UNITS

chamber in each tank has a capacity of 70,200 cu.ft. and is provided with six hoppers from each of which sludge may be drawn through an 8-in. cast-iron pipe. The sludge will be dried on sand beds, a portion of the present sand filtration area being used for this purpose. Each hopper is an inverted pyramid 30 ft. square and has 1 on 2 slopes. Perforated water pipes will be placed on each slope for the agitation of the sludge.

The effluent from the Imhoff tanks flows into four pairs of dosing tanks discharged intermittently upon the trickling filter. The time of discharge will be three minutes. The trickling filter has an area of 14 acres and a depth of 10 ft. Distribution of the tank effluent is accomplished by 2,940 full nozzles and 60 half nozzles of the Worcester type. These nozzles discharge under a variable effective head of 7 ft. to 1 ft. and are spaced 15 ft. apart. There are seven inspection galleries in the filter, four of which have inverts acting as main collecting drains. Precast cement mortar beams set on sills form a grid floor having an air space of 43 per cent. A detail of this floor construction is shown by Fig. 3.

Four secondary tanks, each 60x120 ft. and 15 ft. deep, have a detention period of $1\frac{1}{2}$ hours and a total capacity of 1,750,000 gal. These tanks will have hopper bottoms similar in design to those of the Imhoff tanks. An effluent channel 2,500 ft. long conveys the final effluent to the Blackstone River. A laboratory building will be erected at a point near the Venturi

meter and be fully equipped to make regular analyses.

Plant—Decision to utilize local sand and stone required a large installation of plant. The map, Fig. 1, shows its arrangement. In addition to aggregate for the concrete tank work the construction of the trickling filter alone required 225,000 cu.yd. of crushed stone, ranging in size from $1\frac{1}{2}$ in. to 3 in., and the manufacture of 2,000,000 cement mortar beams, 16 in. long, 4 in. wide and $1\frac{1}{2}$ in. thick. These items presented the greatest problems and it was considered advisable to open a quarry, erect a crushing plant and

FIG. 3—DETAIL OF TRICKLING FILTER FLOOR

Over three miles of track are used in the entire plant layout. Four 9-ton steam locomotives and seven 6-ton gasoline locomotives are in operation the greater part of the time. The maximum grade on track, which is in constant use, is 4 per cent. Three lines of track parallel the Imhoff tanks and come beneath the cableway span. One track on the south side of the tanks is used to transport material to the work at a high

FIG. 6—BRACKETS FOR TOP LIFT OF WALL FORMS

level, while the track immediately north of the tanks serves a similar purpose at a low level. The latter track also handles the mixed concrete from the 28-S mixer. The third track is at the high level and is used by batch trains serving the mixer.

A carpenter shop with all necessary machinery was erected to the west of the Imhoff tanks at a point where there was ample space for piling lumber. Used lumber is returned to a saw installed near the tanks and is used where short lengths are required.

The principal piece of hoisting equipment on this work is a cableway, with movable towers, having a span of 374 ft. and a lifting capacity of 4 tons. This type of hoisting equipment was selected for the construction of the Imhoff tanks and has proved to be well adapted for this type of construction. It is easily and quickly moved by its own power. When removing forms and falsework which were to be moved ahead on the work they were piled on the front of the platform of the towers and moved ahead with them. It was an easy matter to keep the concrete fairly level in the forms. Much of the concrete was of such a stiff consistency that a chuting plant would have been useless.

FIG. 7—CLAMP FOR TIE RODS FOR WALL FORMS

A 28-S mixer was used while concreting the heavy section work, the set-up of this mixer being so arranged that batch cars could be dumped into the batch hopper. Trains of six batch cars receive measured quantities of stone and cement at the crushing plant and cement storehouse and later take on measured quantities of sand from bins located near the mixer. Three trains are constantly serving this mixer. Sand of excellent quality is obtained on the property, the charts being loaded by Fresno scrapers through a trap in an overhead platform.

By a short extension of the New England Power Company's high-tension line and the installation of transformers, electric power was available and has been used for the crushing plant, compressor, cement beam plant, cableway, concrete mixer, carpenter shop and pumps. Seventeen motors with a total of 550 hp. are in use. This power is extremely satisfactory and reliable. Only one serious interruption of service has been experienced, this being due to an ice storm of unusual severity. The loss of the power was of no importance as it was impossible to proceed with the work for several days.

Construction—The difference required in elevation between the surface of the sewage in the Imhoff tanks and the surface of the final effluent is 25 ft. In order to obtain sufficient fall through the plant it was necessary to lower the level of the Blackstone River at Hull Brook. The river level was lowered 3 ft. by excavating a new channel as shown by Fig. 1. This excavation was made by two steam shovels, one passing the material to another located on the bank. In addition to the excavation of the new channel about 500 cu.yd. of ledge were removed which almost completely blocked the course of the river. During this work the river water was diverted to an old barge canal which formerly connected this city with tide water. The excavation for the effluent channel was then made, thereby lowering the water table at the site of the trickling filter about 4 ft.

Practically the entire site of the Imhoff tanks, dosing tanks, trickling filter and secondary tanks was a thickly wooded swamp having a gravel bottom overlaid with peat varying in depth from 2 ft. to 12 ft. Two steam shovels loading narrow-gage trains were used to re-

FIG. 8—FALSEWORK FOR TRANSVERSE WALL FORMS

FIG. 9—OUTFIT FOR CONCRETING FILTER WALLS

move the peat. Good foundation material was several feet below the subgrade of the filter area. This was brought up to grade by backfilling with gravel which was allowed to settle and later rolled. The bottoms of the Imhoff tanks are about 7 ft. below ground-water level. A 5-in. electrically driven centrifugal pump has easily and economically taken care of the water. As soon as the excavations for the hopper bottoms were completed the subgrade was roughly plastered with 2 in. of concrete in order to preserve the shape of the excavation. The hopper bottoms were constructed by using stiff concrete well tamped and finished with 1 in. of cement mortar. At first forms were used but they proved expensive and difficult to place and the results were not always satisfactory.

Panel forms $7\frac{1}{2} \times 10$ ft. in size, Fig. 4, were used extensively on the tank wall construction. These were of fairly heavy construction, $1\frac{1}{2}$ -in. planks being used instead of boards. Some of these panels have been set twenty times and are still in good condition. The walls of the tank were constructed in three lifts, the forms being supported and sway-braced by brackets attached to the preceding lift as shown in Figs. 5 and 6. Rods and clamps of $\frac{3}{4}$ -in. steel were used to tie the forms for concreting. These rods were pulled, the forms removed and brackets fastened to the wall by $\frac{1}{2}$ -in. rods and clamps. A new rod clamp, on which a patent has been granted, was developed on this work and has proved very satisfactory, Fig. 7. This clamp has a cam-shaped face by means of which it may be tightened against the form by temporarily using another clamp which is a duplicate of the first. This is accomplished by locking the cams on two of the clamps and tightening the setscrew on the outer clamp upon the rod. The clamp nearest the form is then rotated by applying a wrench on the hexagon forcing it against the forms. The setscrew on this clamp is then tightened and the outer clamp removed. The clamp is provided with an ellipse-shaped hole by which a wedging grip is secured on the rod without bending it. The forms and concrete for the transverse walls were supported by falsework as shown in Fig. 8. These frames were set on wedges and re-used. This wall was placed in two lifts, the second lift forms being supported by a staging clamped to the first lift of the

wall. The panel forms for the vertical gas vent walls were supported by pieces clamped to the second lift of the transverse walls. This method of supporting forms saved considerable falsework which would have been difficult to erect owing to the sloping hopper bottoms and the fact that they were nearly always flooded.

A 1:2:4 concrete mixture has been used on nearly all the work. The concrete was mixed at a central mixing plant, discharged into controllable form buckets and run on a narrow-gage track to the cableway by which it was placed in the forms. While the cableway was handling a bucket of concrete the locomotive returned to the mixer with the empty bucket for another batch. This system worked out well as both operations required about the same time. Walls running at right angles to the cableway were concreted by moving the towers, the concrete being placed in several walls during one operation. In the case of thin walls the concrete was shoveled into the forms by hand, no attempt being made to place it directly into the forms by the bucket.

Concrete work on heavy wall sections was continued during the winter, the panel forms being boarded on the outside of the studding and the space packed with straw. The top of the wall was protected by tarpaulins under which live steam was exhausted for 48 hours. Concrete was not placed in forms on days when the temperature was below 15 deg. F. at 8 a.m. It was estimated that this cold weather work cost from 25 per cent to 30 per cent additional and was carried on in order to advance the construction as fast as possible and to retain a large part of the working force. No attempt was made to concrete walls of light section during cold weather.

The sedimentation slopes are constructed by means of the cement gun, the gunite being shot against a form. The slopes are 3 in. thick and well reinforced with triangular mesh and diagonal rods. The mixture used is 1:3, but owing to the rebound, which is largely sand, the material as actually placed is estimated to be approximately 1:2 $\frac{1}{2}$. The sand and cement is passed through a $\frac{3}{8}$ -in. screen before being placed in the gun. A rough coat $2\frac{1}{2}$ in. thick is shot first, followed by $\frac{1}{2}$ in. of finish. The finish coat is troweled with plastering trowels. This work is done under canvas in order to protect it from too rapid drying and sudden showers

FIG. 10—CONCRETING SILLS, TRICKLING FILTER FLOOR

which might damage fresh work. The covers are left on for 5 days, during which time the slopes are frequently wet down. Experience indicates that this is essential to good work. The forms for this work were set on wedges in order to guard against possible damage to the work during the removal of the forms. In order to concrete about 3,000 ft. of wall which will enclose the trickling filter a mixer was placed upon a raised platform and provided with an extended skip track, Fig. 9. Platform and mixer are removed on rolls.

The 4-in. concrete floor and the sills of the trickling filter floor are concreted by means of buggies and one-bag mixers. A steel form for the sills, Fig. 10, which keeps its shape and is easily filled was designed on this work. Before dumping the crushed stone of the filter upon the beams it is necessary to carefully place about 6 in. of stone in order that the drains will not become clogged due to stone falling between the beams. When this work was done by hand-placing it was found that there was a tendency of the workmen to fit the stone together thereby destroying the air space of the floorings. In order that these stones might be dumped upon the beams from wheel-barrows and the drains be kept clear, sheet-iron pans 8 ft. long were placed in the drains to catch falling stones. These pans are moved ahead and cleared of stones as the work progresses. It is essential that the stone of the filter be kept as free as possible from dust and fine stone. Screens of 14-in. mesh were placed on blocking 6 in. above the floor of the dump cars which transport the stone from the crusher bins to the bed. In this way a false bottom is formed which retains the dust and fine stone. After the stone has been dumped the cars are run off the filter and dumped to the other side which removes the dust and fine stone.

Will Not Abandon Severn Tunnel

The published statement that the Great Western Ry. of the United Kingdom is planning to abandon the tunnel under the Severn River is denied by an official of that railway. This engineering marvel of 1886, in the course of industrial progress has become a limiting factor in the most expeditious handling of the increasing traffic movement between England and South Wales. The plan to bridge the Severn from Beachley to Aust is simply to provide an auxiliary route. It is the intention to continue to utilize the tunnel to the maximum of its capacity for an indefinite period to come. With the coming of electrification at no distant day, the one objection to the use of a tunnel nearly five miles long will be overcome in the elimination of smoke. The cost of maintaining the tunnel has been remarkably low and it requires very little attention per day despite the fact that it has been in use more than 37 years. The detailed arrangement for the bridge probably will be announced in the near future. The structure will carry four lines of track and a broad roadway for vehicular traffic. It is expected that the government will be a heavy contributor to the cost of the bridge as there is almost as great need for additional highway facilities between England and South Wales as there is for an auxiliary railroad route. The railroad company is insisting on the construction of a bridge with sufficient clearance to make a draw-span unnecessary. This probably will mean that a clearance of 60 ft. at high tide will have to be provided. The cost of the structure is expected to be \$25,000,000.

Height Limits for Chicago Buildings

AN INCREASE in the height limit of buildings in the "loop" or business district of Chicago is made practicable by a decision of the corporation counsel to the effect that the new zoning law is superior to the city's old building code. That code limited the total height to 400 ft., including a tower, and also limited the height of main structure to 260 ft. At present the only building which exceeds that limit is the Chicago Temple Building, which houses a Methodist church and is surmounted by a steeple tower or spire extending to a height of 556 ft. This construction was made possible by a special city ordinance, based on the ecclesiastical purpose and design, while the spire gives little obstruction to light or air. In designing the new Straus Building a 10-story rectangular tower was provided, rising above the 22-story main building and having its roof 475 ft. above the street level. Objection to this was made on the part of the city, but the objection is disposed of by the legal opinion noted above.

Under the zoning ordinance (reviewed in *Engineering News-Record*, May 31, 1923, p. 958) the height of main building in the loop district is fixed at 264 ft. No maximum height for a tower is specified, but there are certain restrictions. Under this ordinance the tower of a building having the dimensions of the Straus Building might extend to a total height of 565 ft. The limitations of tower design under the building code and the zoning ordinance are as follows:

Floor Area—Building Code: In no case shall the area of the tower exceed 3,600 square feet.

Zoning Ordinance: The area of the tower at its base shall not exceed 25 per cent of the area of the lot on which the building is erected.

Width—Building Code: The tower shall not exceed in width one-fourth of the street frontage of the building on which it is erected.

Zoning Ordinance: The face of the tower shall not exceed 50 per cent of the street frontage of the building.

Volume—Building Code: The area of the tower shall in no case exceed 15 per cent of the area of the building upon which it is erected.

Zoning Ordinance: The volume of the tower is limited to one-sixth of the total volume of the building measured in cubic feet.

Height—Building Code: In no case shall the height of the tower exceed 400 ft. above the street level.

Zoning Ordinance: This ordinance makes no mention of any limitation of height. The height of a tower is governed by the provisions indicated above.

Cornices and Parapets—The old building code permitted a cornice projection of 5 ft. The new zoning ordinance provides that at the top of a building the cornice may not project more than 2 ft., but it allows the cornice to be increased beyond the 2 ft. to a maximum of 5 ft. on a sliding scale, depending upon the distance below the height limit that the cornice is placed on the building. This ordinance also places a limit of 8 ft. on the height of parapets. There was no such limit clearly stated in the building code, with the result that there are said to be parapets 30 ft. in height in Chicago.

Alley Set-Back—Another regulation provided by the zoning ordinance is the set-back along the alley frontage of buildings. In the downtown district no wall of a building may be erected nearer to the center line of an alley than a line beginning at a point in the middle of an alley and leaning toward the building line 1 ft. for each 10 ft. in height.

Tractor and Checker at Work on Durham State Land Settlement

Federal Land Reclamation: A National Problem

5. After Reclamation, Organized Land Settlement

By GEORGE C. KREUTZER

Superintendent, Durham State Land Settlement, and Executive
Officer the State Land Settlement Board, Durham, Calif.

*The fifth of a Series of Articles on the History
and Performance of the Great Government Adven-
ture in Irrigation of the Arid Land of the West.*

What Mr. Kreutzer sets forth in this article is based on more experience than that derived from the two California settlements. In 1909, after a period with the Reclamation Service, the author went to Australia with Elwood Mead and worked with him in land development for the state of Victoria. They established 32 settlements there. Careful observation of the conditions and problems of this work forms part of the background of the present article. Readers interested in the early history of the Durham settlement will find a useful account in *ENGINEERING NEWS-RECORD* of Dec. 5, 1918, p. 1014, under the title "Developing Irrigated Land with Selected Settlers."—EDITOR.

IF AN IRRIGATION project is to succeed, the payment for land irrigation works must come from the sale of the products raised on the farm. This means that the settler must make a success of his farming, and his success in turn is dependent on getting his farm into full production at the earliest possible time. The common belief that good soil and an adequate water supply are all that a settler needs to start farming is a fallacy. Much more is needed; the settler's problem has just begun when the engineers have finished the canals and put water on the high corner of the farm. But reclamation has been mostly engineering. Little or no attention has been given to the aid and direction of settlers, and no financing of the settlers has ever been done in this country.

The development of raw land to the point of satisfactory production is expensive. The erection of farm

cottages and barns takes time and money. Yet the family must be housed and land must be graded and farm ditches built in order that irrigated crops may be grown. If there is only one pair of hands to do all the work, something must remain undone; the farm work usually suffers and a cropping season is lost. Moreover, grading land, building ditches, and erecting farm buildings are not farm work. Many farmers have neither the skill nor the inclination to do it well or effectively.

Some Neglected Matters—Careful selection of settlers, intelligent guidance, assistance with money for worthy projects, and the organization of co-operative marketing are some of the things that have been neglected. Community spirit and a desire to co-operate with one another must be encouraged to accomplish for the individual the things that he can not do for himself. Collective bargaining must be a part of the plan. Co-operative purchasing and co-operative marketing must be done when and where they are economically sound. When none of these things is done for the settler he may scratch out a living but he is rarely able to pay interest on the cost of his farm or reclamation charges, much less on the capital debt.

Small farms well tilled and efficiently equipped are the kind that pay. When raw land was cheap and taxes and irrigation charges were low it was not so important that the whole farm be immediately put under intensive cultivation. Returns from crops that could be pro-

duced with little work and capital were sufficient to meet fixed charges. But under present-day conditions, in order to colonize successfully settlers must have long-term credits and enjoy low rates of interest to purchase their farms and make needed permanent improvements and to provide live-stock and equipment. There is nothing new or experimental in supplying such credit. Holland, Denmark, Great Britain, Germany, Italy, France and Australia loan money to settlers at rates of interest from $2\frac{1}{2}$ to 4 per cent and for periods of from 40 to 98 years. The loans are not subsidies, simply loans; but as such they form the vital feature in a workable plan. These countries realize that their social, economic and political salvation are dependent on a home-owning population. Denmark has been converted from a country of tenants to one of home owners in less than half a century—the result of a sound land settlement policy.

California Settlement Law—In this country no attention was given to organized land settlement until California passed its state land settlement act in 1917. It provided long terms on the purchase price of the land; loans for effecting improvements and for the purchase of live-stock and equipment; and service in farm engineering, animal husbandry, orcharding and other branches of agriculture. Aid and direction were to be fully utilized.

Two settlements have been established: one at Durham, comprising 6,400 acres, upon which 143 families are located; and the other at Delhi, of 9,000 acres, upon which 270 families are located and which finally will accommodate 360 families. The Durham settlement was established in 1918 and the one at Delhi two years later.

Developing Durham—The land for the Durham project was a portion of a large cattle ranch, with a skeleton irrigation system. Accurate soil and topographic surveys were made, followed by the subdivision survey. The farms were not the customary rectangular 20, 40 or 80-acre units but were of such size and shape as the character of the soil and topography indicated would be best adapted for farming and the kind of settlers who were likely to settle upon them. Proposed irrigation ditches and drainage courses were made boundaries of farm units. This minimized the construction of ditches and structures. The ease with which a rectangular farm may be worked means nothing if it is traversed by a diagonal ditch. The tract was divided into 109 farm units of 96 to 300 acres each, and 34 farm laborer's allotments of 2 acres. The price of the land was fixed according to soil type and topography, based on the productivity of the soil and the cost of bringing raw land to full production; it ranged from \$48 to \$245 per acre, which included a paid-up water right and full construction costs. As the survey stakes were put in for farm ditches the agricultural program proceeded rapidly. Farm laterals were built, land was graded and alfalfa sown. Areas that could not be made ready for alfalfa were sown to grain.

In June, 1918, the first 60 farms were thrown open for settlement; 900 acres of alfalfa were established and over 1,200 acres of wheat and barley were ready to cut by the end of June. All farms had not been planted, but those that were proved most popular with the applicants; they realized the benefits to be gained from buying a farm where harvesting would be the first agricul-

tural operation. The planting work was charged to each unit at cost, and grain crops that cost an average of \$9.50 per acre brought returns to the settlers as high as \$40 per acre one month after settlement. The returns per farm varied from \$326 to \$2,015, with a full summer season ahead in which to grow crops.

What Was Asked of the Settler—The terms of sale were 5 per cent of the selling price as a deposit and the balance payable in 40 semi-annual amortized payments which included interest at 5 per cent per annum. Thus a \$5,000 farm could be purchased for \$250 down and forty half-yearly payments of \$190 each. A 40 per cent deposit on permanent improvements was required, the balance being repayable similarly to the balance due on land.

The Board set the minimum capital a settler should have at \$1,500—more would be better, of course. Live-stock or equipment was considered as part capital. That capital was not the only asset a settler should have was fully recognized. He must possess agricultural experience, industry and good health, and generally be of such character as to make the highest use of the unusual opportunity offered. It is believed that no plan can be successful where citizenship alone is the only requirement; many failures must result from it. Agricultural experience is necessary to put energy and capital to their highest uses. Successful farming is closely coupled with hard work, careful living and a habit of husbanding resources seldom found in other occupations.

Advising the Settler—On each application for a farm, consideration was given to the kind of farming the applicant would follow and how he would develop the farm with his limited capital and the state's assistance; farms were granted to those most likely to utilize the opportunity offered. When possession was given conferences were held with those needing help and a program was agreed upon that would put the farm on a paying basis as early as possible.

The farmstead engineer, who was a trained architect and recognized rural building requirements, designed the settlers' houses, barns and other buildings to fit in with each settler's limited pocket-book. He got them the most for their dollars: structures of architectural merit, convenience and cheapness and at the same time adapted to additions without costly alterations. Conferences between the superintendent, the farmstead engineer, the settler and his wife often resulted in the abandonment of an expensive house plan and the substitution therefor of something cheaper but sufficient for their needs. Farmstead layouts were made showing the proper location of house, barn, garden, poultry runs, family orchard and corrals. This service prevented the settler from making costly mistakes and provided neat farm layouts. Natural advantages in topography and growing trees were made use of.

Each settler was furnished a contour plan of his farm upon which were located farm ditches, check banks and proposed structures. Since the contour interval was 6 in., most of the engineering service could be given from the plan, thus reducing field work to a minimum. This service does away with guess-work.

At least once each year the settler's assets and liabilities are summed up and his net worth determined. At the same time an operating statement is made estimating the next year's income and expenditure. This

is done primarily for the settler's information and secondly for the information of the administration—credit cannot be extended without such statement. To get data for the statement a thorough inspection of the farm must be made, and it is found that at such times the most helpful suggestions can be made for the betterment of the farmer's condition. His economic problems can only be solved when all of the facts are known.

The Settlement Act provides that up to \$3,000 may be loaned to a settler upon the security of permanent improvements, live-stock or equipment. Much less is loaned to him if he can get through without the full amount. It should not be made too easy to get money, or difficulty will be experienced in getting it back. The farmer should be made to recognize his obligations and make an honest effort toward meeting his debts. This means a proper division of the farm income between the financing body and the farmers as the operators of the farms.

FIG. 1.—A PLANNED FARMSTEAD AT DURHAM

Borrowings—Loans may be made on permanent improvements up to 60 per cent of their value and are repayable in 40 semi-annual payments including 5 per cent interest. Likewise, loans on live-stock and equipment are granted, when needed, up to 60 per cent of value, repayable in 36 monthly payments.

Nearly all of the settlers at Durham and Delhi have borrowed some money. Many would not have survived had provision not been made for this credit. It would have been the usual story of spending their own money and still the farm would not be on a paying basis. They would need a little more money and at best could get a short-time loan with no chance of meeting it at maturity: a few months or a year of this struggle and another abandoned farm would be left as a monument to an unsound land settlement policy.

Few people realize how costly it is to bring a farm into full production. An analysis of six of the best dairy farms at Durham shows that the cost of barns, fences, grading, alfalfa, ditches, hog houses, dairy equipment, domestic water system and other necessary improvements, not including the house, amounted to \$119 per acre for a 30-acre unit. The cost of dairy cattle, hogs and other live-stock amounted to \$85 per acre, and equipment and farm tools amounted to \$20 per acre. This is more than \$200 per acre and still the cost of the land and house must be added. The live-

stock investment may seem high, but it takes good cattle to produce profit; scrubs won't do. However, the figures are not alarming when understood.

These farmers made a larger return on capital investment than do those not so well equipped. The investment was not all needed at once, and a considerable portion of it was made from income; but all six farmers had borrowed money from the state. It can therefore be readily seen that loans for improvements, live-stock and equipment speed up the development program and hasten the approach of the time when the farmer shall become self-supporting.

How One Loan Helped—A young couple settled at Durham and had \$3,000 capital. They purchased 41 acres, of which 36 acres were in alfalfa. The cost of the grading, ditches and alfalfa was \$1,640, on which they paid down \$656. A comfortable cottage cost \$1,500, upon which was loaned \$900. The settler built his own barn at a cost of \$600, and purchased a team, wagon, cow and heifer, harrow, plow, rake, mower and other tools costing \$850. Initial deposit on land was \$461.50. He had to have a well and hand pump and \$140 worth of lumber for chicken house and other outbuildings. His expenditures to this time were more than his original capital and he would have been in debt had he not sold his first cutting of alfalfa. Soon a half yearly payment would be due the board. Before the second cutting of alfalfa was harvested an inspection of the property was made. The alfalfa was past the stage of making good cow hay. The family was called upon and the young wife said that her husband was driving a tractor in a neighboring county, while the alfalfa had been let to a neighbor on shares. The neighbor was busy cutting his own field, and counted on spare time to farm the neighbor's field, where he got only half the crop. After several questions were asked, the young wife admitted that they were "broke" and a tear coursed down her cheek as she related that they had never been entirely without funds before—Of course they hadn't! They wouldn't have had \$3,000 in the bank when he was 35 and she 29 if they had not been saving and careful. A conference was arranged and the husband sent for. At the conference a program was agreed to which provided for the purchase of sufficient dairy cattle to utilize the feed. The cattle purchased could be added to their assets and give ample security. The following week they had 11 high-grade cows instead of two, and they were on the pay roll. Their first week's check from the Dairymen's Association amounted to \$48.47. They had borrowed \$1,110 to make the purchase of cattle, payable in 36 monthly payments of \$33.30 each. One week's check would meet it and leave \$15 to buy groceries. His loans at that time amounted to \$2,994.

That live-stock note was paid on time and the farmer and his wife have progressed; their net worth increased from \$3,000 in 1918 to \$8,149 at the end of 1922. A loan at the right time rescued a somewhat hopeless situation and this family can now look forward to the future with confidence. And so nearly every settler's progress is a story.

Land For Laborers—There is no definite type of farm laborer in this country. Itinerant laborers drift from the grain belt to the fruit sections and finally congregate in the large centers during the winter and spend their scanty savings. Few are married, and if

they are it is a difficult struggle for parents and children. This is an unsatisfactory condition; the laborer should be a home owner and live under his own fig tree and vine. It rivets him down and gives him the same satisfaction and ideals possessed by the farm owner; he becomes interested in taxes, schools and community improvement. His children have the same self-respect and independence as the children from the farm homes, and these children are going to be the farmers of the future. Hence a place was made for the farm laborer at Durham and Delhi.

The laborer allotments are 2 acres in area and the same purchase terms are given as on the farms. Laborers were accepted as settlers on these allotments if they had the initial deposit. Except in two cases, they had an average capital of less than \$200. When they could not pay the 40 per cent cash deposit on their cottage, but had skill in the use of tools, the materials were bought by the state and the labor furnished by the purchaser (generally labor on such buildings is equivalent to 40 per cent of the total cost).

At the end of 1922 these laborers had increased their assets from \$6,000 to \$39,000, or an average of more than \$1,000 each. They are independent and owe nothing that is due; four have completely paid for land and improvements. No farm laborer has failed. The few who left did so because they were offered permanent work elsewhere that seemed attractive. One who came with \$20 left three years later with \$1,400 in his pocket. Another, a carpenter, who came with \$150 at the age of 48 years, now has a five-room house, barn, vineyard and berry patch, cow, poultry and small tools, a Ford to take him to his work, and total assets valued at \$2,700. In short, the farm laborers have worked hard because they could see daylight, because conditions had been made favorable for the economic and social growth of the laborer and his family.

Community Matters—At both Durham and Delhi the settlers were organized into a co-operative association to take care of their social and business needs. Through the association, purchasing was done in carload lots. Cement, posts, wire, seed, fertilizer, and many things that were needed for the development of their farms were bought and distributed at cost. No attempt was made to buy groceries or personal effects. The association acted as the clearing house for the community. Specialists from the University of California gave talks on tuberculosis in cattle and its control, management and care of poultry, pruning, deep tillage, and other timely subjects.

California is favored in having many agricultural commodity co-operative marketing associations—raisin growers, prune and apricot growers and a score more. These associations are state-wide. The Durham and Delhi settlers utilize them where their products can be marketed in that way. When products are produced in sufficient quantity and no association exists to market the product a small co-operative is organized if it is economically sound to do so.

There was no co-operative association to handle the dairy products at Durham. It was discovered that a good whole milk and sweet cream market could be developed. At first a small hand separator was rented and the first week's sales amounted to only \$40, but the business grew to \$100,000 per year. The dairymen own a

modern plant and produce milk and cream of high quality. The plant and equipment have been paid for by charging dairymen 5c. per pound of butter fat and 1½c. per gallon of milk. After the deductions were made the dairymen received more for their product than if they had sold their product independently.

The Result as a Whole—Thus two settlements were established where the settler worked with better tools, owned better live-stock and had mobilized for him all the skill and science of modern agriculture. Because many of the things mentioned have been lacking in land settlement heretofore, too many settlers and projects have failed.

The plan outlined and functioning in California is

FIG. 2—GETTING HIGH FARM PRODUCTIVITY THROUGH DAIRYING

Herd of Jim Braden at Delhi, Calif.

not a panacea, but it is a better way of doing it than any other way tried. People of industry, character and energy, together with reasonable capital, can and do succeed. While much is provided by the state, still the individual must do his part. He must avoid pitfalls in agriculture that ruin many.

I have no patience with men who complain that ten or a dozen dairy cows are slavery. They are not. They are an anchor to keep people from skylarking around the country when they ought to be at work. Any of us, if we expect to be of any use in our chosen line, must keep our noses to the grindstone. The study of successful people in any community proves this, hence it has been our aim at Durham to have our people engage in a kind of agriculture that is safe, in which the dairy cow plays a large part in the prosperity of individuals, insuring that the fertility of the land will be maintained, as well as bringing the farmer a ready income.

Dr. Mead, chairman of the State Land Settlement Board, said of the policy applied at Durham and Delhi: "It is a radical departure from the methods of the past. The day of the speculative land buyer is gone. The day for the creation of communities, organized for teamwork in business, in farming and in social advancement, must soon come. There has never been in the history of the world a greater opportunity to create a high rural civilization than can be achieved in the United States under a planned development by utilizing the knowledge, ability and experience of all its people."

[The next article in the series will appear in the issue of Nov. 29.—Editor.]

Composite Foundations for Large Temple Building

Concrete Piers for Column Groups—Concrete and Wood Piles Elsewhere—Underpinning for Original Footings

HEAVY FOUNDATIONS including a combination of concrete piers and concrete and wood piles, together with a concrete dome over a large basement area, are required for the Bahai temple now being built at Wilmette, Ill. An exceptional feature of the work is that after the pile footings had been built they were underpinned to give the required carrying capacity. A general description of the structure is necessary for an understanding of the foundation conditions.

The building will be a nine-sided structure about 150 ft. in outside diameter with a central space 72 ft. in diameter and 162 ft. high from the main floor to the top of a dome. This dome, with a rise of 49 ft., will be composed of steel ribs and framing and beneath it will be an ornamental ceiling dome of similar construction. Around the central space and forming the outer part of the building there will be nine rooms or compartments 40 ft. wide, one of which is assigned to stairways giving access to the galleries. At the base of the dome will be a drum or ring girder supported at nine points by groups of four columns. With the galleries and other interior structural work the foundation load at each of these points will be about 810 tons.

Nine concrete piers 6 ft. in diameter and carried down to rock at a depth of 120 ft. below the ground constitute the foundations for the central part of the building and the steel dome. At the top, each 6-ft. pier is flared out to form a rectangular cap or footing 11 x 9½ ft., as shown in Fig. 1, to provide support for four steel columns, as noted above. It will be seen that owing to

FIG. 1—FLARING HEAD OF FOUNDATION PIER CARRIES FOUR STEEL COLUMNS

the shape of the building these columns are placed eccentrically on the footing. Steel reinforcing is used in the flaring column cap. Upon the cap is a grillage composed of nine I-beams in one direction and six in the other direction, the latter being grouped three under each pair of columns.

Spread footings would have been permissible for the lighter loads of the outer structure around the central

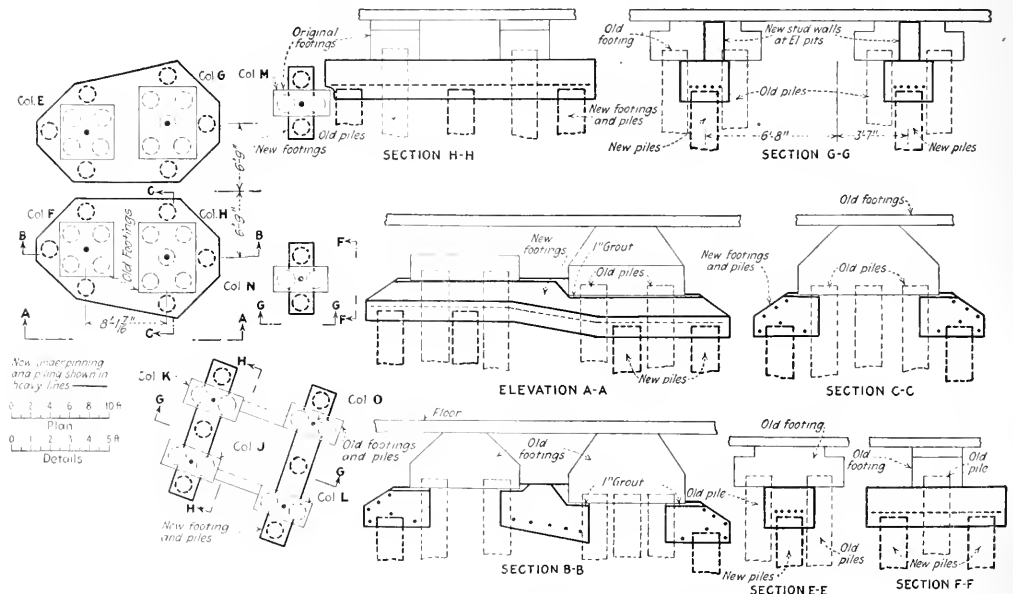

FIG. 2—COLUMN FOOTINGS REINFORCED BY UNDERPINNING

area. But to provide for greater security against settlement, in view of the fact that the central foundations are rigidly supported on rock, it was decided to use concrete piles 18 ft. long for this part of the work. It was recognized that in general it is not the best practice to combine two different types of foundation in one structure, but it is believed that in this case both types are so secure or stable that there will be no movement or settlement sufficient to cause cracks or distortion in the superstructure.

Construction difficulties were encountered with both types of foundation. Water was the great difficulty in

these caps forming underpinning for the original footings, as shown in Fig. 2.

Piles of composite construction were used for this reinforcement of the outer foundations. In the first place, timber piles 35 ft. long were driven to such depth that the tops were approximately 20 ft. below the ground line. Then a concrete shaft 16 in. in diameter was poured in place on top of each wood pile and extended up to the underside of the concrete footing. These new piles were tested and showed ample supporting power.

A foundation dome for the main floor area is another distinctive feature of the work. In the basement a

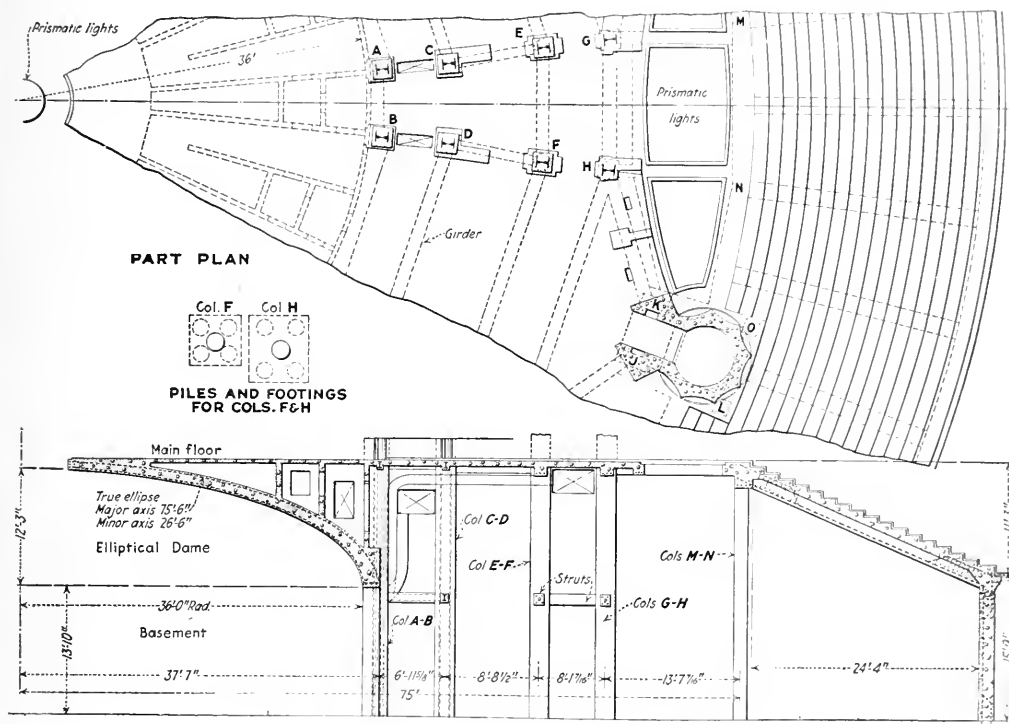

FIG. 3—FLOOR DOME AND FOUNDATION COLUMNS

the pier foundations, which were constructed in wells 6 ft. in diameter, sunk through clay and gravel. At a depth of about 80 ft. below the surface, water was encountered in considerable quantities so that the work could proceed only very slowly. At times three steam pumps were used in a single well to remove the water fast enough to permit digging. All of the wells were finally landed successfully on bed rock and then filled with concrete to elevation of base of steel columns.

Concrete cast in place and consolidated by dropping heavy weights was the method used for the concrete piling, but on testing some of the piles it was discovered that they would not carry safely the loads for which they were designed. Further examination showed that the piles had not been put in according to the prescribed method. As a result it became necessary to reinforce all of the minor footings. This was done by driving additional piles and placing concrete caps upon them,

clear space was required 72 ft. in diameter and unobstructed by columns. To meet this requirement a concrete dome is provided as shown in Fig. 3. This is formed as a true ellipse having a rise of 12 ft. 3 in. and giving a total clear height of 26 ft. from basement floor to crown. It springs from the concrete casing of the nine groups of steel columns, already mentioned. As this dome is regular in shape and is uniformly loaded, its design and construction did not involve particular difficulties. Its shell is 12 in. thick, reinforced near the inner and outer surfaces by a network of radial and circumferential rods. The floor load which the dome is designed to carry is 100 lb. per square foot.

The general plans and models for the building were prepared by Louis Bourgeois, architect, New York, with H. J. Burt, Chicago, as consulting engineer in the structural and foundation design. The foundations and basement were completed just before the winter of 1922.

The Four Refuse Disposal Plants of Paris, France

Contractors Collect Mixed Refuse in 700 Motor Trucks and Deliver to Sorting, Screening, Grinding and Destructor Plants Operated by Another Company—Fertilizer, Brick and Electricity Produced

BY RUSSELL L. WILLARD

Assistant Technical Director, "Traitement Industriel des Residus Urbains," Paris, France

IN PARIS, the different kinds of refuse from a population of about 3,000,000 are not collected separately. All ashes, garbage, and other household residue or rubbish, as well as matter from the markets and certain street litter, are taken up together. Street sweepings have most generally been flushed into the sewers. Since the war the collection has been made every day and at one time only, early in the morning. This method of a total collection daily is expensive but very satisfactory.

The collections are made in some 700 motor trucks

Paris, the companies may use their trucks, under certain conditions, for other purposes or they may collect refuse in the suburbs when the city of Paris agrees to receive suburban refuse. Actually the city receives in its plants considerable quantities of refuse from the suburbs, some of which still is transported by horse-drawn vehicles.

The refuse is hauled to four disposal stations, all of which are now operated by a single company. At these stations there is some variation in methods of treatment, but the method most generally used, which has been adopted for the enlarged stations under construction or proposed, is sorting, screening and grinding, the coarse screenings going to destructors and yielding heat that is converted into electric current and clinkers that are made into brick, while the fine screenings go to farmers for use as fertilizer. Only three of the four plants have destructors, with a combined capacity of 46 metric tons per hour. Enlargements in progress at two of the disposal stations and the provision of furnaces at the one which lacks them will bring the destructor capacity up to 122 metric tons an hour. A further increase to 160 tons an hour in the near future is probable.

It should be clearly understood that of the total amount of refuse collected actually not half goes to the furnaces, the rest is picked from the sorting conveyors and goes to agricultural land, or, in some cases when the plants are overcharged, a part is sent to special discharge areas. The comparative percentages of these divisions vary enormously with the season but in what follows it will be made clear that the city of Paris intends eventually to be equipped to burn all the refuse collected daily in the city as well as a large part of that taken up in the suburbs. Many large farms to the north of Paris receive the refuse fertilizer regularly each year but whether the farmer will pay and how much he will pay depends upon the supply in the market and it is dangerously easy to get overstocked with this kind of product.

Historical—Until 1899, the refuse of Paris was disposed of by teaming contractors who negotiated with the suburban farmers for the reception of their loads. A large percentage of this refuse was used as fertilizer. In 1899, a private company, the Société des Engrais Complets, established a plant at St. Ouen (see map, Fig. 1) for the treatment of refuse. The process consisted in sorting out tin cans, bottles, old iron, etc., and in grinding what remained. This considerably reduced both the volume of refuse and the railroad freight charges. In its new form the refuse had a much less repulsive aspect, was sought after by farmers and brought prosperity to the disposal company. In 1904 and 1905, the Société des Engrais Complets opened two other plants, one at Issy les Moulineaux, the other at Romainville. The success of the pioneer company did not go unnoticed and in 1905 another company built a plant at Vitry.

FIG. 1—LOCATION OF PARIS REFUSE DISPOSAL PLANTS
City pumping stations for water and sewage use large amounts of electric current generated from steam raised by heat from the destructors.

which are owned by private companies. At present there are three companies that supply trucks with their chauffeurs for this service. The city indicates and directs the itinerary and answers for the loading of the refuse. The contracting companies are required to have a reserve supply of trucks representing one-fifth of the total; that is, the regular service is carried on with four-fifths of the trucks at the disposition of the city. The city of Paris has, in case of emergency, a reserve of 200 trucks of its own which may be put into immediate use. Every truck is motor-driven and of about five tons capacity (metric tons or tons of 1,000 kilograms used throughout this article). The remuneration of the companies is calculated from the number of trucks held daily at the disposition of the city and the distance covered by those that are used. Each of these items has a unit price but it is agreed that these prices shall be varied according to the salary that the companies are forced to pay the chauffeurs, the market price of gasoline and the amount of the current government tax on automobiles. Once the collection is made for

Incineration—Just before 1906 some changes took place that affected directly the trade in refuse fertilizer. The price of sugar fell and in addition certain legislation discouraged the general cultivation of sugar beets, the cultivators of which were the most important buyers of ground refuse. The resulting inconveniences were immediate, and, to meet the difficulties, the S. E. C. was encouraged by the city to equip its three sorting and pulverizing plants with incinerators. Each incinerator consisted of three groups of Meldrum furnaces of 75 métric tons capacity in 24 hours, one battery at each plant being considered as a reserve. These incinerators were completed in the following order: St. Ouen, August, 1907; Romainville, December of the same year; Issy, February, 1908.

Poudro—At Vitry no incinerator was installed. The original company began operation at a bad time and the plant went under the control of another group in 1907. This new company, La Société des Engrais Organiques, supplemented the sorting and grinding process by screening the ground refuse. It was possible to find people who would take without charge the part retained on the screens, if it was given to them, and the fine matter was sold at a rather good price, under the name of "poudro." The first production of poudro is mentioned because screening has since been considered more important than grinding in the preparation of marketable fertilizer. The sale of poudro compelled the S. E. C. also to install screens in 1909. Fig. 2 shows a typical cylindrical screen and Fig. 3 shows the screened product as compared with ordinary refuse.

The competition in the sale of refuse as fertilizer, the increasing annual tonnage to be disposed of, the growing population of the suburbs, the more numerous restrictions imposed by the suburban mayoralties against the disposal of Paris refuse within their boundaries, and the consequent rise in the cost of transportation, soon made the first incinerators insufficient.

Existing Plants—The execution of the city's program of 1910 may be considered substantially as having brought the equipment of Paris to where it is today, although several changes have been made since July, 1922. The refuse is delivered to four plants, well located (see map) to shorten the haul of the collected

FIG. 2—REFUSE SCREEN AT IVRY PLANT, PARIS

St. Ouen Plant—The collecting trucks dump into a long pit, Fig. 4, the bottom of which is provided with belt conveyors. In passing along the conveyors the refuse is sorted. Among other things set apart is an enormous quantity of tin cans and boxes which are pressed, baled and sold (see Fig. 5). The conveyors discharge the refuse into elevators, which deliver the refuse to cylindrical screens. The fine screenings are sold as fertilizer and the coarse matter is passed on to the furnaces. The grinders previously mentioned are still a part of the installation, but their greatest utility now is simply to reduce the volume of the refuse when the plant is overcharged and it is found necessary to get rid of a few cart-loads by rail.

The original Meldrum furnaces have been transformed into Boussange furnaces and in addition five batteries of Heenan & Froude furnaces of six cells each have been constructed. The incineration capacity is thus about 500 tons per day. The heat combustion from the incinerators is used to produce electricity for plant purposes and for sale.

Clinker—The furnace clinker is drawn or pushed out in a block and moved by a traveling crane to a crusher, which in turn feeds a series of roller mills and screens. The ground clinker is fine enough to be used for brick making. Considerable quicklime is contained in these cinders, but this becomes slaked if they are left stored in piles for some months. If it is desirable, as is often the case, to use the clinker immediately, treatment is necessary. This consists of passing the clinker into huge metal cylinders, which are rotated slowly as steam is introduced. On leaving the cylinders the clinker is relieved magnetically of the large percentage of metal

FIG. 3—UNSCREENED AND SCREENED REFUSE OR "POUDRO," PARIS

refuse. The plant at Vitry was abandoned. The plants of St. Ouen and Issy, since 1910, have been the mainstay of the disposal system, and St. Ouen, in particular, will not suffer in comparison with any plant in Europe in regard to the quantity of refuse treated and the efficiency of the exploitation. The standard method of French treatment today is best described by outlining the procedure at St. Ouen.

FIG. 4—ONE OF 700 REFUSE TRUCKS DUMPING IN PIT AT ROMAINVILLE DISPOSAL PLANT

fragments which it contains. After mixing with lime the material is fed to the presses by means of a helicoidal screw. The raw brick are baked by steam.

During 1922, the St. Ouen plant received approximately 235,500 metric tons of refuse, 52 per cent of which was burned. Nearly 90 per cent of what remained (or some 43 per cent of the original volume of refuse) was taken by the regular customers as fertilizer. Electric current totaling 9,500,000 kw.-hr. was produced over and above the uses of the entire plant. Of this current 68 per cent was taken by the city sewage pumping stations and the rest was sold to private companies. About nine million bricks were sold at a price slightly below that of the ordinary red clay brick. In short, since the war the St. Ouen plant has gained money for its stockholders and economized for the city of Paris.

St. Ouen (see layout plan) is the oldest of the Paris plants. It was developed little by little. There are details in the operation that do not conform to the most modern practice. These will be modified in the installations that are now under construction.

Unfortunately, all the plants have not the same record as St. Ouen. No other of them has found such a good market for refuse as fertilizer. The plant at Issy follows exactly the same process as that described for St. Ouen, but the incineration capacity is not so large. Romainville is not equipped to make brick and the incinerator is even smaller than at Issy, while at Ivry no refuse is burned. The program of 1910 provided furnaces at Romainville in addition to those in use, as well as an incinerator at Ivry, but these installations were a failure. These last were a sort of cupola furnace with revolving grate about a vertical axis. Their complete abandonment was due to the impossibility of making function the apparatus provided for the ejection of the clinker, the furnaces clogging after being a short time under fire.

The New Program—The contract of July, 1922, for the exploitation of the existing plants provides for their control by a single corporation, the *Traitement Industriel des Residus Urbains*. The company is forced to receive the entire collection of the city and there is a penalty for every ton not disposed of by the company. On the other hand, a price is paid to the company per ton received in the plants, which price varies with the market price of the kilowatt-hour sold by the large lighting and power companies. Receipts from the sale of the products of sorting, sifting or grinding, of the

electric current, of brick, etc., go to the company to defray the expenses of exploitation. The city has an option on all the current produced up to and including the total needs of the pumping stations and pays the market price for such current.

The company is allowed to earn $6\frac{1}{2}$ per cent on its capital account, under the conditions noted above. A deficit or profit recorded by the company at its annual closure of accounts is considered as an increase or economy made by the company in the subsidy accorded by the city per ton of refuse received by the plants and in the case where the company just makes expenses $6\frac{1}{2}$ per cent is paid on the capital actions as previously mentioned. When a profit is recorded, this profit is divided between the city and the company in such a manner that as the profit increases the amount due the company is finally limited. In the event of a deficit, the $6\frac{1}{2}$ per cent payable to the stockholders is diminished in proportion to the deficit until it is 4 per cent. The company is guaranteed 4 per cent on its capital, however, whatever may be the deficit.

Enlargements—A contract for the enlargement and modification of the equipment has been accepted by the city and part of this work is already under way. The expense of this work is covered by bond issues by the company and guaranteed by the city, the city reserving the right to buy any portion of the bonds. The city may eventually and as especially provided in the contract inherit all the installations old and new.

The incinerators of the cupola type at Ivry and at Romainville that were not a success, are being replaced by other furnaces, and the new ones are nearly completed. These furnaces will be ready to operate this winter. The resulting increase to the capacity of incinerators at Romainville will be two Bréchet furnaces of four cells each and one of two cells. At Ivry the new installations will consist of three Bréchet batteries of four cells each and six Boussange groups of two cells each. The original three Meldrum furnaces at Romainville have since the first of the year been fitted with Boussange cells and are again in service. Each of these two plants is to be provided with equipment for making brick from clinkers.

The transformation of furnaces mentioned in the foregoing is not meant to imply any adverse criticism

FIG. 5—BALED REFUSE, METAL AND WOOD, READY FOR SALE

of these older installations. The original Meldrum furnaces had already been in use fifteen years. During this time it was found advisable to divide these furnaces into batteries of separate cells. With this modi-

fication these furnaces were more adapted to work with a forced draft and the manipulation of the clinker became more convenient.

The Boussange and Bréchet furnaces are both of French manufacture. The existing furnaces of each type have given very satisfactory results and it is natural therefore that these furnaces should appear in the new installations rather than additional furnaces of foreign make. In both the Boussange and Bréchet furnaces the refuse is introduced by means of a cylindrical chute fixed at the top of the furnace. Each chute is provided with a mechanism to regulate the quantity of refuse falling in order not to extinguish the fire. In the Boussange incinerator the refuse falls directly onto the floor of the cell; in the Bréchet it falls first upon a preliminary drying shelf, from which it is raked into the furnace proper. Both are arranged to run with forced draft, which at the same time protects the cast-iron

and with one pair held in reserve. Its incineration capacity will be about 1,200 metric tons in 24 hours. The electric plant will have three steam turbines of 5,000 and one of 1,000 kw. capacity, with steam raised entirely from the refuse incinerated. The entire installation attached to the existing plant for converting clinkers into brick will be doubled.

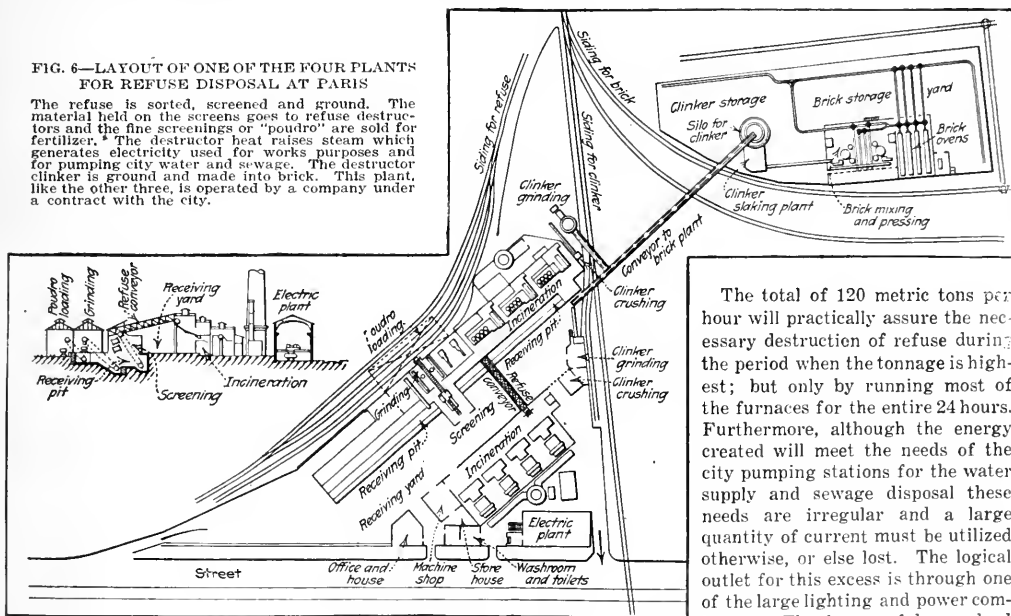

No immediate changes are contemplated at the St. Ouen plant although the turbines may be replaced later by new and larger units.

The additions to the incineration capacity may be summarized as follows:

INCINERATION CAPACITY IN METRIC TONS PER HOUR			
Plant	January, 1922		December, 1924
St. Ouen	20		20
Issy	12		62
Romainville	14		20
Ivry		20
Total	46		122

FIG. 6—LAYOUT OF ONE OF THE FOUR PLANTS FOR REFUSE DISPOSAL AT PARIS

The refuse is sorted, screened and ground. The material held on the screens goes to refuse destructors and the fine screenings or "poudre" are sold for fertilizer. The destructor heat raises steam which generates electricity used for works purposes and for pumping city water and sewage. The destructor clinker is ground and made into brick. This plant like the other three, is operated by a company under a contract with the city.

The total of 120 metric tons per hour will practically assure the necessary destruction of refuse during the period when the tonnage is highest; but only by running most of the furnaces for the entire 24 hours. Furthermore, although the energy created will meet the needs of the city pumping stations for the water supply and sewage disposal these needs are irregular and a large quantity of current must be utilized otherwise, or else lost. The logical outlet for this excess is through one of the large lighting and power companies. The hours of heavy load

envelope of the cell. This envelope being hollow, the air before penetrating the small holes in the bottom is directed around it, making an air jacket. The clinker is extracted from the Boussange furnace in a block by a hydraulic or steam pusher. The Bréchet has a revolving cell which may be inverted, thus throwing the clinker out.

These furnaces burn something more than one ton per hour and they may be counted on to produce steam at the rate of from 75 to 110 per cent by weight of the weight of Paris refuse burned, depending upon the season. The calorific value of Paris refuse is distinctly inferior in the summer to the refuse collected the remainder of the year. This drop is due to the profusion of green vegetables and fresh fruits in summer and the lack of household stove and furnace ash.

At Issy les Moulineaux, a completely new plant is to be built beside the existing plant. The new plant will have ten Boussange batteries, of five cells each, constructed in pairs one on either side of a steam boiler

made necessary by the demands of the ordinary consumer of electric current must therefore be considered. To meet this condition the destructors must be capable of burning the total daily collection of refuse in less than 24 hours. The problem is being studied at the present time and before long the total of 120 metric tons per hour designated as the capacity for the immediate future may be increased to a capacity of 160 tons per hour.

Small Water Mains in Denver

One-sixth of the 54,911 water taps in Denver are on the 100 miles of 2-in. water lines privately owned and 19 miles municipally owned. It is not the policy of the board of water commissioners to lay 2- and 3-in. mains where it can be avoided but to pursue any other course than to lay these sizes when it means a small size or nothing is considered by the board bad business and would work a hardship on many people.

Through the Reclamation Country

By F. E. Schmitt

Associate Editor, *Engineering News-Record*

THIS is the eighth of the series of letters written by Mr. Schmitt during a journey recently made through the West in which he visited irrigation projects, studied developments, and interviewed builders, operators and settlers, in order to present to our readers the actualities of reclamation as revealed to an unprejudiced investigator.

The series of letters began in the issue of October 4.

Yuma, Ariz.

FROM THE situation on many of the projects it appears that if reclamation consisted only of irrigation and settling of vacant public lands it would be a simpler matter. But the fundamental formula assumed at the time the Reclamation Act was framed, namely,

arid public lands + public water + federal irrigation works = farm land available for homesteading

does not apply in most of the actual cases. The formula is complicated by added terms, which often tend to become predominant. In the great Southwest, a big extraneous factor consists of international water claims, since the two great streams of the region, the Colorado River and the Rio Grande (which the people south of the line call Rio Bravo), belong in part to Mexico. There are also competing state claims to water. An even bigger factor of trouble is the power question, which cannot be settled by businesslike negotiations leading up to a treaty, but calls for the formulation of broad public policies. Still another factor is flood protection, or, more broadly, river control. These four combine in the problem of the Colorado River, the biggest fighting problem of the West, and in the last analysis one of the biggest of the whole country.

Private Land Complications—A complication of quite different kind affects practically all the reclamation projects. This is the inclusion of privately owned land in the projects and the existence of prior water appropriations, which often took up more than the available summer flow, so that the government had to depend on storing flood waters. Nearly always, also, there existed private irrigation, covering the best part of the irrigable region and pre-empting the most favorable canal routes. These conditions, supplemented by diversity and conflict of water-right laws, gave rise in the early days of reclamation to a vast amount of trouble, unsatisfactory bargaining, and hard feelings; and some effects of these hard feelings survive. The actual record of nearly every reclamation project is therefore a tangled snarl of negotiations, agreements, purchases, and exchange of water or rights, often difficult to see through and containing occasional elements of injustice. Sometimes private interests in a strategic position drove a sharp bargain with the government, and sometimes it was the government that drove the sharp bargain. Unification of water ownership and distribution in a given region, which in general is desirable or even necessary for best utilization of the water, was not always feasible. The Service, being subordinate to state laws, had too little power to compel unification, and in consequence it was sometimes led into actions

that may account for the charge that the Service was hostile to private irrigation. But, whatever griefs resulted from the unavoidable conflict of interests between the federal enterprise and private rights and from their jockeying and unfairness, they have all been chalked up against the Reclamation Service.

Yuma and the Colorado—For the present the other complicating factors are of more concern. There is a good case right here at Yuma. The lower valley on the Arizona side was long subject to overflow by the Colorado River, and to protect it a levee was built; but every May and June the river becomes so boisterous that a hard fight must be waged to protect this levee. The people complain much of the river-protection cost, and want the government to take care of it. Actually, the cost of the levee has already been paid by the Service, and deducted from the settlers' charge. But the annual expense of fighting the river, \$90,000, represents an assessment of \$1.50 on every acre of the projects, which doubles the yearly charge to the settler. Should this cost be taken over by the government? The settlers say emphatically yes.

Flood dangers and the cost of fighting them are not peculiar to Yuma, however. Districts above here are affected, and, in addition, there is the huge, unsolved problem of the lower river, where it flows through Mexico and both supplies and threatens the Imperial Valley. Also, silt is an important part of the matter. The river water is so turbid as to deposit several feet of silt each season in the Imperial canals even 50 miles or more from the intake. This means large maintenance cost; but the real menace of the silt is that it piles up as an inland delta in the lower valley and causes the river to run wild. The Imperial district has protected itself temporarily by making the so-called Pescadero cut, but this is probably only a short-time solution. Everybody hereabouts knows instinctively and positively that a single, unified treatment of the river is necessary, as furnished by the Boulder Canyon dam; and they need it urgently, and hope it will be built soon.

Whether flood protection benefits conferred by such a structure should then be assessed on Yuma and Imperial is a different question, however, not simply because of the serious burden it would place on the land, but because of the physical magnitude of the Colorado River problem as well as its interstate and international phases, which make it so decidedly a national matter that the Yuma people cannot see it any other way. The question of sharing irrigation waters with Mexico enters as an important element of the problem; the present arrangement of the Imperial Valley with the southern republic does not provide for all future needs, and as the doctrine of priority of beneficial appropriation of water which holds between the states (theoretically) has not been established as between the two countries, the relative rights are uncertain. So long as the river is uncontrolled, the rights will of necessity remain undefined and will be a constant source of worry and mutual recriminations.

Power Ownership—Just as the great dam scheme for the Colorado depends in part on power development and has given rise to much knife work in the West and in Washington over the ownership of this power, so also there is or has been fighting over power benefits in other places—Minidoka and Salt River, for instance—and there is an important power element in the Rio

Grande case. Unless a basic policy concerning power is soon established by Congress, such fighting may become the central feature of the whole reclamation problem. But it is important that in defining that policy, Congress should also establish quite unmistakably the ownership of present power in reclamation systems. The extreme farmers' advocates seem to think that everything should be made an appendage of irrigation: if irrigation storage also serves as power storage, they want the entire power revenue to be credited to the irrigation, as was done in Salt River, where the entire operating and maintenance cost of the irrigation system is covered by the power income. Presumably, in a case where the power revenue is large enough, it might even pay a bonus to those who reside on the irrigated lands—reside, rather than farm, because they probably would not farm under those conditions, and it might be just as well to omit building the irrigation canals. In the meantime, wherever there is power in connection with reclamation, the farmers do not concede that the government owns this power or that it may be sold to any one else, but they hold that it is their property by natural right, because the dam was built primarily for supplying their irrigation water.

An Arizona Scheme—State claims inject further life into the Colorado River case (and practically the same thing might be said of any other interstate stream in the arid West). This is illustrated by a very recent happening in Arizona. A filing has been made on a very large block of river water—some 20,000 sec.-ft.—by parties who are believed to be close to the state government. In support of this filing a scheme has been proposed for irrigating 2,000,000 or 3,000,000 acres (much more than is included in the famous Columbia Basin scheme) by a water system that puts all past conceptions of canals, tunnel and flume systems to shame altogether. One alleged reason for claiming so much water is that arid Arizona includes half the drainage area (*area*, be it noted) of the Colorado, hence the state is entitled to half the total flow. The argument may be absurd, but it probably could be supported just as strongly as some of the water claims that have been made by other states, for instance Colorado in defending diversions that deprive other states of water. The Arizona filing ought to make good horse trading whenever a new interstate agreement on the Colorado River problem is placed on the green table.

Offhand it is hard to see why this "navigable" river, of very great size and presenting in every one of its aspects so great a problem that it is undoubtedly national, is not *in toto* a national stream and is left subject to the capricious notions of various states. On the other hand, Los Angeles sweeps aside all notions about geographical rights by making a bid for some of the Colorado River power (after the United States Government shall have developed it by building a dam) in order to further upbuild the territory surrounding what one enthusiast called the "wonder city." And, to make the picture complete, various corporations also want the Colorado River power, for their profit.

Internationalism on the Rio Grande—Flood protection, power, and international and interstate water rights complicate irrigation in the Rio Grande case as seriously as in that of the Colorado, though in different proportions. There is a special complaint along that stream, however, due to a peculiar historical incident.

An agreement was made twenty-five years ago between the United States and Mexico that 60,000 acre-ft. of water should be delivered each year below the international dam free of charge to Mexico. For this purpose Congress appropriated (on the account of the State Department) \$1,000,000 toward the Elephant Butte dam costs; the proportionate share of the dam costs would be less than this, but the remainder would provide for operation and maintenance expense. On this latter point the farmers are not satisfied, and in the arithmetic by which they back up their case they go to the length of charging up part of the operating cost of their own distribution laterals against Mexico, which kind of figuring will probably hurt their case when the matter comes up for serious consideration. At any rate, they ask for another \$1,000,000 as a gift from the national government, and, remarkably enough, A. B. Fall, when Secretary of the Interior last year, favored his own state of New Mexico by recommending such an appropriation. Congress did not pass it, being very busy.

Just at the present moment the Elephant Butte dam is in the public eye in another way, that has some relation to the back history of the matter just mentioned. A concession to build a dam on that site was granted by Congress to a private company in the nineties, with a right to all the flood waters of the Rio Grande, *gratis*, though Mexico laid claim to some of the waters of the river. Later, this concession was voided by the court for non-completion of the work, though it is alleged that acts of the U. S. Government made it impossible for the company to proceed with its work. After this happened, the people of the valley strongly importuned the Reclamation Service to build a dam there for irrigation, and still later the State Department urged the Interior Department to build a dam for carrying out the Mexican treaty provision. The Reclamation Service then, with the help of the State Department's added million, built the present dam, so that it appears everybody should be satisfied. But now comes a claim by a British subject who had had an interest in the dam concession, for loss on account of the voiding of the concession. The government's expert in its defence of this suit is Arthur P. Davis.

Overburned Lime Causes Plaster "Popping"

Lime which has been overburned or which has been burned during hydration is the cause of popping in plaster, tests made at the Bureau of Standards have shown. In this type of failure small particles appear to expand and push themselves out of the plaster, leaving tiny holes. In extreme cases these holes may be sufficiently large or numerous to be unsightly. It has been shown that popping will not be serious if the lime is ground fine enough to pass a No. 50 sieve, as in that case the lime will be completely hydrated during the mixing and application, or else the particles of defective lime will be too small to cause noticeable holes. These tests were made in co-operation with the National Lime Association, the Contracting Plasterers Association, and the International Plasterers Union. Ninety-eight panels were erected containing different impurities in different sized particles. It was found that, with the possible exception of sand, impurities other than overburned lime did not cause popping no matter how coarse they were.

City Problems Discussed by A. S. M. 1. at Atlanta

Many Engineering Topics Discussed by American Society for Municipal Improvements, Atlanta, Ga., Nov. 12-16, Include Responsibility as to Health, Pavement Design, Newest Ideas in Street Lighting

Report of Committee on Street Lighting

BY RALPH TOENSFELD

Chairman, Committee on Street Lighting; Engineer,
Division of Street Lighting, St. Louis, Mo.

PROBABLY the most interesting developments to the larger municipalities who have ornamental systems under consideration is the asymmetric lantern. It consists of a frame in the usual lantern form in which are mounted glass panels of a slightly diffusing character. Within this lantern and surrounding the incandescent lamp is mounted a cylindrical prismatic refractor whose prisms are so designed as to give an asymmetric distribution, that is, a non-symmetrical distribution. This new development not only sends the upward light from the lamp downward so that it will be useful on the street surface but in addition reclaims, to some extent, the light which is ordinarily thrown onto the lawns and front porches bending it outward onto the street, thus avoiding the undesirable strong light on the front porches and increasing the illumination of the street. Experiments indicate that with this type of unit a given minimum illumination can be produced at a considerable saving in energy over systems formerly in use, and furthermore, that an unprecedented uniformity in illumination can be obtained with a minimum number of units.

Another development which will interest municipalities which hold to the center suspension type of unit in some districts, is the four-way reflector. This is essentially a suspension type of unit based upon somewhat the same principles as the asymmetric above described except that it produces four beams of light at an angle of 90 deg. with each other, instead of two. It is made to be suspended over the center of intersecting streets throwing its maximum beam up and down each street. It is a highly efficient and very economical unit for such uses.

A third development which may be useful in undeveloped territories which are traversed by heavily traveled highways is the highway lighting unit. There are three types of these on the market today, essentially different in principle but all aimed to produce the same results. They are designed for a mounting height of from 25 to 35 ft., a spacing of from 300 to 400 ft. and will produce a fairly uniform illumination of low intensity almost entirely confined to the surface of the roadway. The illumination produced by this type of system will be sufficient to obviate the necessity for light glaring headlights, thus eliminating one of the most potent sources of accidents.

The Why and How of Street Lighting

BY STEPHEN CARLETON ROGERS

Commercial Illuminating Engineer, Street Lighting Department,
General Electric Co., West Lynn, Mass.

IN THE luminous or magnetite arc lamp, the light is given off by the arc flame or the vapor stream which conducts the current across the gap between the copper electrode, which is practically non-consuming, and the composition electrode, which is encased in a metal tube. The light is produced by electro-conduction of particles of the light giving materials given off by the negative (composition) electrode. The other type of light source is the Mazda C lamp, which produces light by high temperature incandescence.

As an illustration of what might be accomplished in the

way of highway lighting from an economic point of view take for example Massachusetts (and the same might apply to any other state). There are at present roughly 1,500 miles of improved state highway, which should be scientifically lighted. This would mean an initial investment of about \$5,000,000, with a yearly maintenance cost of \$1,500,000 (figuring an average cost of \$60 per lamp year to the city or state). A few years ago drastic headlight laws were enacted, which it has been conservatively estimated cost the automobile owners more than \$2,500,000 at that time, plus the additional amount necessary for their upkeep. If this money had been expended in the proper direction, headlights would be unnecessary and safety to all would have been increased.

Traffic Control—On account of the vast amount of travel and vehicular traffic on our main streets and thoroughfares, some means must be employed to control or regulate it in order to further protect life, property, and the rights of each and all of us. For this reason, there have been developed a great number of various types of traffic lights or signals, etc., some of which are purchased outright by the city, some by the police department, etc. Since these devices are installed in the street, over the street, on the street or adjacent to the street, this type of unit logically should be a part of the street lighting system and controlled and owned by the central station (or by the electrical department if a municipal plant), a rate being made on the basis of a 24-hour service.

* * *

The Cost of Adequate Street Lighting

BY L. A. S. WOOD

Manager Street Lighting Section, Westinghouse Electric & Manufacturing Co., South Bend, Ind.

IT IS generally conceded that the cost per capita for an adequate street lighting system should not be less than one dollar, and yet, an investigation into this subject disclosed the fact that there were only nine states in the Union in which the per capita expenditure of municipalities for street lighting exceeded 90c., and only four where the expenditure was more than \$1. At the time the investigation was made, it was found that the average expenditure for the whole of the United States was 71c. per capita. (Report of the Lighting Sales Bureau, National Electric Light Association, 1921.)

The cost of adequate street lighting systems can often be reduced if the street lighting improvement schemes are carried out under a comprehensive program co-ordinated with and included in city zoning plans. A scientifically derived, comprehensive, far-sighted street lighting program correlated with a city zoning plan is not easily worked out. It calls for specialized talent in many lines of work, and, in most cases, city officials can profit by bringing into consultation the engineers found in public utility companies, whose success depends largely upon their ability to foresee future requirements and to meet them with a minimum loss in reconstruction. This nation is becoming possessed of many vast cities and most of them—like "Topsy"—"just grew." Our large industrial establishments and other privately owned projects exemplify the economy of employing talented engineers and architects. The city is, of course, more important than any of its contributing factors; and it is unfortunate that some of our cities do not appreciate the necessity of providing sufficient appropriations for this type of personnel.

Possible Causes of Failure of Pipe in Sand Sewage Filters

BY HARRISON P. EDDY
Consulting Engineer, Boston, Mass.

WORCESTER, Mass., has the most extensive intermittent sand filters of any city in the United States, the net area being 66 acres. For underdrains, precast cement-concrete pipe, laid 35 ft. apart, were used. The mix was relatively dry and the pipe was carefully cured. The Worcester sewage is heavy with acid pickling wastes from wire and other iron and steel plants.

Iron was precipitated in the beds, clogging them and making it necessary to dig up the underdrains. Some of the pipe went to pieces. It was found that grooves had been formed spirally around the pipe, in such fashion as to suggest that the grooves followed the layers of the wet concrete as the shell was built up by tamping.

Three explanations of the disintegration of the pipe were offered: (1) Effect of underground water in the peaty soil in which trenches for the pipe were dug, these trenches having been backfilled with sand; (2) acid in the sewage, equivalent to 1 lb. sulphuric acid per 165 gal. of sewage; (3) putrefaction of sewage in the pores of the sand beds, due to the sulphur which occurs in all sewage or due to the pickling wastes in the sewage, either of these producing sulphuric acid.

The Engineer's Responsibility in Malaria Prevalence

BY L. M. FISHER
Associate Sanitary Engineer, U. S. Public Health Service,
Columbia, S. C.

MALARIA, one of the most widespread diseases according to Sir Ronald Ross, causes in the aggregate more human sickness and misery than any other illness. The engineering profession must take the responsibility for causing a large part of this illness and death together with the heavy loss occasioned by the disease. Today, in the United States, engineering works are being constructed which will cause many persons to have malaria who would otherwise not have had it. Their efficiency will be greatly lowered for weeks or months and a recurring attack years hence may again result in a considerable economic loss to the persons who suffer and to the communities in which they live, and even death may ensue for some.

Dr. Carter, the foremost authority on malaria in this country has repeatedly stated that in many localities half of our malaria is man-made. Railroad builders have placed many culverts too high, and they have left many borrow pits undrained. The highway engineers engaged in building good roads are making the same mistakes. Paradoxical as it may sound, there have been drainage works which have temporarily caused an increase of malaria, either by obstructing small water courses with spoil from the large drainage ditches or from new breeding grounds for malaria mosquitoes caused in times of low water by large, wide ditches on nearly flat grades, or by both conditions. Hydroelectric developments have very frequently caused an increase in malaria prevalence because of the almost innumerable new breeding places caused by large bodies of impounded water created without regard to the conditions which permitted mosquitoes to breed profusely and entirely unhindered by the numerous aquatic enemies which are to be found in old pools or in pools properly constructed and cared for. The municipal engineer has some interest in this problem for his own water supply reservoirs may offend in the same way as a storage reservoir for a power company.

One of the sharpest outbreaks of malaria in South Carolina occurred in Greenville ten or twelve years ago, in a section of the state where little malaria prevailed at the time and where little exists now. It was attributed to the installation of storm drains and catchbasins all over the city. Prolific malaria mosquito breeding occurred in these

basins and, augmented by the breeding from nearby river flats, causes a rapid spread of the disease. Instances have been reported where faulty drainage of irrigated land was responsible for an outbreak of malaria. Leaky water tanks on railroad property have caused breeding places to develop in towns and because of their location close to houses have contributed to the malaria mosquito population. Abandoned rock quarries, and even quarries in operation, containing pools of water, gravel pits along the roadside, old phosphate rock mines, abandoned rice fields, have all contributed generously to man's misery because of the malaria pestilence they have spread among persons living in the vicinity.

In some sections of the South the work of the engineer has locked up the agricultural resources of many square miles of country by making a section relatively free of malaria an intensely malarious one so that people were forced to sell or abandon their property and move away. When we stop to recall that agriculture is an industry on which many other industries are based the tremendous economic damage that is occasioned by such a procedure becomes apparent.

Relation of Depth of Foundations of Pavements to Their Strength

BY CLARENCE D. POLLOCK
Consulting Engineer, New York, N. Y.

USUALLY in city streets the most satisfactory foundation is one of portland cement concrete, commonly mixed in the proportion by volume of 1:3:6 and generally laid 5 or 6 in. deep upon a well compacted subgrade. Where the subsoil is sand or sufficiently porous material to provide good drainage, these depths have proven sufficient even for present day traffic. Some cities have had a tendency to lay heavier foundations, but with good subgrade material it would seem to be expensive insurance.

When the subsoil is of clay or other material which cannot be readily drained, it would seem advisable to improve the subgrade rather than to weight it with a heavier foundation. A dry clay is usually capable of sustaining a load of five tons per square foot, but when very wet the same clay may not sustain more than one ton per square foot. By excavating a few inches more and refilling with sandy or gravelly material the load will be spread so that with this and the better drainage a much greater load may be supported.

The foundation cannot act as a beam until the subsoil gives away sufficiently to allow it to act as such. The better the subsoil the greater the load required to deform the foundation. The Washington tests show that with the subgrade support the sustaining power of the concrete foundation varies more nearly as the square of the depth than directly as the depth.

Measurements show that the foundation in transmitting the load to the subgrade does not transmit it so that the pressure intensity is uniform. The pressure intensity is highest directly under the load, and spreads out over a considerable area, diminishing to nothing at some distance from the load. The intensity of pressure under the load must exceed the bearing value of the soil underneath before the foundation can act as a beam. Even a macadam, bituminous macadam or bituminous concrete foundation will not be deformed until the intensity of pressure directly under the load exceeds the bearing value of the subsoil. If the load is stationary or if the surface of the pavement is very smooth there will be simply the static pressure, but if the surface of the pavement is a little rough there will be impact and if the surface is quite rough this impact may amount to four to five times the static pressure. This is greatest when the tires are badly worn. With good well cushioned tires the impact apparently approaches more nearly the static load, and hence the advisability of securing as uniformly smooth a surface to the pavement as possible in order that the impact of moving loads may be eliminated as completely as can be done.

In the Bureau of Public Roads tests with slabs on wet

and dry soils, the impact tests punched through the 4-in. slabs, but those 6 in. and more in depth were merely cracked while those 10 in. thick could not be broken by their apparatus even on the wet subgrades. According to this a thickness of 10 in. should be sufficiently great to carry any load that might come upon the pavement even with a wet subgrade which may be more or less plastic. However we are not so likely to have wet subgrades in city streets subject to heavy truck traffic, as the pavement is usually impervious to water and likewise the sidewalks are generally paved so that there is much less likelihood of subsoil troubles here than with suburban roads. But should there be bad subsoil conditions in general it will be found much less expensive to improve the subgrade than to pay for 4 in. of extra concrete in addition to the extra grade removal which alone would in most cases be sufficient when replaced by a more porous coarse grained material which is not affected materially by water as are the very plastic soils such as many clays. With proper support from the subsoil and a reasonably smooth surface to the pavement, a thickness of 6 in. for the concrete foundation seems adequate especially as most heavy loads are now hauled on auto-trucks having rubber tires. The trucking interests have found that it is not economical to carry loads in excess of about 750 lb. per inch width of tires. This insures wide double and triple solid rubber tires on each rear wheel and a good distribution of the load over the pavement so that by the time it is spread through the thickness of the pavement and the concrete foundation the pressure intensity is usually well within the supporting value of the soil. Some states have limited the loads permitted on their highways, but here we have a limit placed by the effect on the truck owners' pocketbook which is more easily enforced.

When in exceptional cases it may be necessary to use a greater depth of concrete than 6 in., it should be remembered that the supporting power of the concrete foundation varies about as the squares of the depths.

Another matter that the tests have brought out is the fact that while the compressive strength of 1:3:6 was 50 per cent of that of the 1:1:3 concrete, the difference between the beam and slab strength of these two mixtures did not exceed 20 per cent.

In addition to damage from heavy loads the pavement including its foundation may be injured by water entering a clayey or other plastic subgrade material from terraces or sidewalks and lifting and cracking the foundation and pavement by the swelling of the subsoil. Sometimes this may be caused by frost heaving the foundation when there is a large amount of water in the plastic soil under the foundation. During the past season the writer was engaged upon an examination of some breaks in foundation and pavement where a study of the conditions shown by openings and the history of the breaks as to when they were noticed after the completion of the pavements and before freezing weather and the soil condition in the terraces on the uphill side and the clay of the subsoil showed conclusively that the breaks were due to the soil conditions and not to loads to which the pavement was subjected.

* * *

Miscellaneous Discussions

Technical Papers—Many technical papers were listed on the program. Some of these are abstracted in this issue, and of the others some are mentioned briefly below.

A plea for more palatable drinking water was made in a paper sent by John R. Baylis, principal sanitary chemist, Baltimore water-works, who stated that if the people want water of that sort it can be provided at reasonable cost. The new water supply of Memphis, Tenn., was the subject of a paper sent by J. R. McClintock, of Fuller & McClintock, and read by Mr. Cunningham, associated with that firm. An entirely new plant, except for distribution system, is being provided at a cost of \$2,800,000. It will be the largest municipal plant in the country taking its supply wholly

from wells. The water will be treated to remove carbon dioxide and iron.

Zoning plans for Atlanta were reviewed by Robert Whitten, city planner, Cleveland, Ohio. Atlanta was the first Southern city to adopt a zoning ordinance some two years ago. Buildings in the business district are limited to a height of 150 ft., partly because of the narrowness of the streets. G. J. Requardt, consulting engineer, Baltimore, outlined the publicity work which paved the way for the Baltimore zoning ordinance.

Sand-clay and top soil roads, with special reference to his own state, was the subject of a paper by W. R. Neal, state highway engineer of Georgia. In sand-clay roads the sand may be regarded as aggregate and the clay or silt as filler. Earlier practice was to give these roads a high crown, as much as 1 in. per foot in some cases, but this has been reduced to as low as $\frac{1}{2}$ in. The latter should be used only where the maintenance will not be good. The lime rock asphalts of the South and their use for paving were described in a paper read by E. A. Kingsley, city engineer, Dallas, Texas. In 1922, some 2,000,000 sq. yd. of this pavement were laid in Texas by the Uvalde Asphalt Co. Besides the mines near San Antonio, some are about to be opened in the Florence section of Alabama.

Sewage and Garbage Disposal—Two papers on night soil disposal were read. One, by Milton J. Ruark and C. E. Keefer, of Baltimore, Md., described the dumping into the sewers of night soil collected in cans from outlying districts. The other, by Mr. Decker, of the Tennessee Coal & Iron Co., Birmingham, Ala., outlined a system of collection by cans, dilution and sedimentation in tanks, and treatment on sprinkling filters, as used for more or less temporary mining camps. In discussion, H. P. Eddy, Boston, said that this is the first case to come to his attention where night soil is converted into sewage and then treated. The Imhoff tank capacity is about 10 gal. per capita, a low figure, but the night soil is free from bath and sink wastes with their loads of grease. The process is not patented.

In a paper on the MacLachlan process of treating activated sludge, J. S. McVea, city engineer, Dallas, Texas, described work now going on at Dallas to perfect the process. After the use of sulphur dioxide for conditioning the sludge before drying the sludge is being passed through a rotary screen press, and then passed between rolls. A new filter press and rolls were installed in June and quite recently the apparatus has been modified. The sludge resulting from the MacLachlan treatment, with a moisture content of about 82 per cent, goes to driers for reduction to 10 per cent. These and other papers on sewage and a series of reports on garbage disposal practice occupied a whole evening.

A paper on valuation of property for taxation purposes, by Walter W. Pollock, Manufacturers' Appraisers Co., Philadelphia, described the Somers' system of valuation of real estate. The author said that by applying scientific methods in like manner to utility rate and purchase valuations the present large differences in the figures set up by the experts of the opposed sides could be eliminated. He would use the reproduction new less depreciation method of appraisal, but based on fixed unit and other standards.

[Further abstracts of papers presented at this meeting of the American Society for Municipal Improvements will appear in an early issue.—EDITOR.]

Hints That Cut Cost and Time

For the Contractor and the Engineer

Mounted Concrete Mixer Saves Time and Labor for Contractor

CONTRACTORS using concrete mixers where portability is desirable may be interested in the experience of George Leavens, of Lansing, Mich., who has been able to effect savings of approximately 25 per cent in labor and even greater amounts in time by the use of a mounted mixing machine. Mr. Leavens mounted a 10-ft. mixer, which is one size larger than the average machine used by contractors on light work, on a speed-wagon chassis obtained from the local representatives of the Reo Motor Car Co.

His knowledge of gasoline engines warned him that it would be far from economical to attempt to run the mixer from the 45-hp. engine of the speed wagon when a 6-hp. gasoline engine would furnish ample power for the work. Using the speed-wagon engine for this work would also have meant wear and tear on transmission parts which might have decreased the life of the chassis by a couple of years. For these reasons a 6-hp. engine was mounted on the rear of the chassis to operate the mixer.

Mr. Leavens saves in labor through the fact the machine can be run into any desired position on the job for operation, eliminating most of the wheeling of mixed concrete. For instance, in pouring concrete for a sidewalk, he drives the speed wagon parallel to the sidewalk, pouring as he goes. The same system is employed in pouring outside foundation walls, while in pouring inside walls, the speed wagon is driven as close as possible to the point at which the work is being done.

MIXER MOUNTED ON SPEED-WAGON CHASSIS

Perhaps the greatest saving in time occurs when one job is finished and the outfit must be moved to another. The jobs are seldom less than a mile apart and are often two or three times this distance from each other. With the mixer mounted on the speed wagon, however, the changes are made in negligible amounts of time.

Unique Two-Level Street Obviates Costly Grading

BY HARRY W. LEVY

Dept. of Public Works, Borough of Manhattan

DUE to the great difference in elevation between Broadway and 12th Ave., two parallel streets in upper Manhattan, New York, near 134th St., the latter street was left ungraded until this year. When it was decided to open the street, two possible methods of doing it presented themselves. The first was to run a uniform grade of 8.3 per cent from Broadway down to 12th Ave., a distance of about 800 ft. The other was to run a nearly level grade from Broadway out to the viaduct which carries Riverside Drive above 12th Ave. at this point. If the first method was fol-

TWO-LEVEL STREET IN NEW YORK CITY

lowed it would necessitate a cut of some 10 to 45 ft. within the street line and ultimately over a considerable area outside. This would be complicated in the future by the fact that the grading of the lots on the north side would require permanent shoring for the rear walls of the buildings on 135th St.

The second alternative would require very high retaining walls at the west end of the block and consequent expensive foundation work for future buildings on the adjoining property unless these retaining walls could be extended over the building line to form the footing for such buildings along their street face. Legal restrictions, however, prevented the city from doing this and it was decided that the best plan was to build low retaining walls for the upper end of the street and then to carry the remainder on a viaduct to connect with the Riverside Drive viaduct and to grade a low-level street connected with 12th Ave. below the viaduct. This latter plan makes it possible for the owners of the lots facing the viaduct to use the lower floors of their buildings which open on the low level street for business purposes and the upper floors for high-class residential purposes.

The economic point at which the street structures should change from filled retaining walls to a viaduct was determined by the relative cost of the two classes

of work and the structures were laid on that basis. House connections for the sewer were carried through the retaining walls on two levels in the east end of the street and then the sewer was run to the lower level in a drop well built into the abutment of the viaduct.

The steel viaduct comprises two four-columned towers, made up of continuous H-columns with horizontal and diagonal bracing supporting the viaduct deck structure. Transverse girders extend over each pair of columns and cantilever some 15 ft. beyond to the building line. To these cross members are framed six lines of longitudinal girders which in turn carry the viaduct deck members. The inner and outer pairs are set higher to avoid a floor slab of varying thickness due to the roadway crown and sidewalk elevations.

At the extreme west end of the new viaduct, where a connection is made to the existing Riverside Drive viaduct, a short cantilever was inserted to avoid increasing the load on the latter structure.

The P. T. Cox Contracting Co. was awarded the contract for this viaduct at the price of \$60,787.50.

Construction work was done under the supervision of the Bureau of Engineering, Department of Public Works, Manhattan, of which C. M. Pinckney is chief engineer and Ralph Lewis, construction engineer. Assistant Engineers Joseph Collyer, D. Nelson West and the writer are mainly responsible for the design.

Tile Drains Collect Water for Small City Supply

THE CITY of Condon, Ore., with a population of about 1,300, is located on a plateau some 2,900 ft. above sea level on which there is no water suitable for a city supply. Except for a small stream called Hay Creek, 700 to 800 ft. below this plateau, the only streams within 15 or 20 miles of the city that might be used after purification lie from 1,000 to 2,000 ft. below city level. For some years a supply was pumped from Hay Creek at a point about four miles from the city; the water was taken directly from the stream without any purification treatment. This source was subject to pollution and when the time came for increasing the supply it was decided to use the natural gravel deposits of the

From Job and Office

Hints that Cut Cost and Time

stream as filtration beds, collecting the subsurface flow in a small reservoir built below stream-bed level from which the water was pumped to the reservoirs serving the city's gravity distribution system. The cost of this work, covered by bond issue, was \$90,000.

The accompanying plan shows the general arrangement of the collection works which consist of a main line of 8- and 10-in. collecting pipe with tight joints to exclude surface water, extending up the creek bed, and several 6-in. agricultural tile lines with open joints placed 6 to 12 ft. below the stream bed and located so as to pick up as much as possible of the flow from springs which form the headwaters of the stream. Measurements in the stream bed indicated a minimum flow below the surface of about 127,000 gal. per day.

The filtering afforded by the gravel backfilling, that was carefully placed over the collecting tile, was not expected to purify the water in the sense of removing bacteria, but rather to give clear water at all times. All pumped water is chlorinated before going into the city distribution system. There are two or three ranches on the watershed above the collecting system and the chlorination is to protect from possible pollution from that source. Since the completion of the system there has been little flood water and hence the degree of clarification that will be secured is not yet known.

The reservoir is a reinforced-concrete box built across the stream bed so as to form a dam and having a water-tight concrete roof so all surface water passes over it. The reservoir has a capacity of 109,000 gal., is about 10 ft. deep, and 34x46 ft. in plan. The walls are 12 in. thick and the roof 5 in. thick.

There are some small springs along the creek bed below the collecting works. Water from these flows into a gravelly backfill on the upstream side of the reservoir. When the reservoir level is pumped low enough, this spring water is admitted through the 6-in. drain-pipes shown, which are at other times closed off by flap valves. The 12-in. pipe under the reservoir was put in

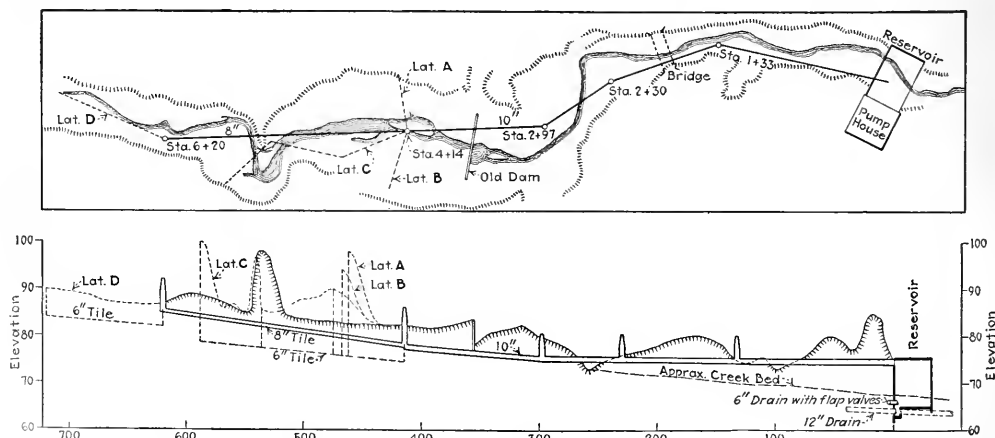

FIG. 1—PLAN AND PROFILE SHOWING ARRANGEMENT OF COLLECTION SYSTEM

From Job and Office

For Contractor and Engineer

primarily to provide a bypass for stream flow during construction and was later made to serve as a drain.

The pump house is built just out of the stream bed and above it at one end of the reservoir just described.

FIG. 2—TYPICAL MANHOLE DETAILS

The floor of the pump house, 17 ft. above the bottom of the reservoir, is considered to be safely above flood level.

The pumping equipment consists of two independent units. Each of these is a 50-hp. modified Diesel engine, direct-connected to a vertical, triplex, single-acting pump. These pumps deliver through 22,000 ft. of 8-in. main against a static head of 723 ft. and an estimated friction head of 57 ft., making a total of 780 ft. The engines operate on oil of 24 deg. Baumé gravity and are guaranteed to consume not more than 0.52 lb. or 0.068 gal. of fuel per horsepower per hour when operated at three-quarter load, which is approximately the operating requirement of the plant. Each pump unit has a plunger displacement of 155 g.p.m. and a nominal rated capacity of 150 g.p.m.

After operation for some time to test out the system the pumps were declared to be wholly satisfactory, operating without vibration and with a minimum of attention. Air chambers specially designed to meet the unusually high pressure requirements were installed, but some doubt is expressed as to whether these afford any advantage. Hand operated bypass lines are provided so that heavy water hammer due to starting and stopping the flow in the 4-mile line can be prevented. The pumps also have pressure relief valves set to operate at a pressure of 400 lb.

The design and construction of the system was carried out under the direction of R. E. Koon of Stevens & Koon, Portland, Ore.

Incline Railways Facilitate Dam Construction in the West

HYDRO-ELECTRIC jobs in the far West that involve the construction of dams or power houses in deep ravines are frequently reached to best advantage by incline railways, on which flat cars, equipped with a heavily reinforced end called a "strong back," are operated with a cable and hoist. To cite three California examples: An incline on the Hetch Hetchy project has a 70 per cent grade and a drop of 1,700 ft.; another on the Big Creek project drops 2,000 ft.; while one used in building the Kerkhoff Dam was 3,000 ft. in length and had a maximum grade of 92.5 per cent.

Long steep inclines are chiefly confined to the larger jobs, such as those just cited. Sharp curvature, on the other hand, is common to inclines on jobs of all sizes, the arrangement of rollers for guiding the cable being similar to that used in logging camps. The accompanying picture illustrates the strength and simplicity of roller-guide construction commonly used on sharp curves. The use of portals instead of posts on the inside of the curve only affords opportunity for the effective use of cable sway-bracing in addition to the batter posts that take thrust directly.

The rollers are made of pipe with special fittings on each end, terminating in solid shafts of considerably smaller diameter. Rollers that carry the heaviest load are made of fairly large size, usually 6 in. in diameter. Both horizontal and vertical rollers are put in wherever the cable would otherwise come in contact with ground or structures. Special attention is paid to fitting the

GOOD PRACTICE IN ROLLER GUIDE CONSTRUCTION
ON CALIFORNIA HYDRO-ELECTRIC JOB
Note grease cups at tops of rollers

bearings and keeping them well greased so friction will be reduced to a minimum. The inclines and their guide rollers are built to handle any load that a "strong back" car can safely transport.

Electrically-Controlled Traffic Signals Adopted in Dallas

By W. J. POWELL

Chief Engineer to the Supervisor of Public Utilities, Dallas, Tex.

TRAFFIC CONTROL in the business district of Dallas, Tex., is effected by means of electrically-operated signals, centrally controlled from a traffic tower at Elm and Ervay Sts. The signals flash alternately red and green lights, at intervals adjusted by the operator to suit traffic conditions, with an amber light and warning bell to mark the changes. This system has been in operation for several months with most gratifying results in the way of speeding up traffic and decreasing accidents.

Except on Pacific Ave., the traffic control signals are suspended over the street intersections at a height of 18 ft. and are served by overhead wiring. Pacific Ave. was formerly occupied by the tracks of the Texas & Pacific Ry., but since the tracks have been removed the street has been greatly improved, all the electrical conductors have been put in conduits below the street surface, the street repaved, and a new lighting system with ornamental standards along the curb has been provided. For this reason the traffic signals on Pacific Ave. are mounted on cast-iron standards, designed to harmonize with the lighting standards, and placed on concrete pedestals in the center of the street intersections. At first there was considerable opposition to placing any such obstruction in the roadway, but this opposition has not been justified by results, as the heavy concrete pedestals carrying the signals serve to separate the traffic lanes and prevent accident. At some points police and fire-alarm boxes are installed on the same standards.

The system is served by underground cables connecting with the central control tower at Elm and Ervay Sts. The concrete pedestals are 30 in. in diameter and 30 in. high above the street grade, and 48 in. in diameter at the base, which is 3½ ft. below street grade. They are heavily reinforced and protected above ground by a ¼-in. boiler plate shell. The standards are painted a dark green and the pedestals bright orange, because of the high visibility of that color under all conditions. Four small red lights mounted on top of the pedestal further mark its location.

The Ashe Electric Co. of Fort Worth had the contract for the installation of the ornamental lighting system and for the conduits and concrete pedestals of the traffic control system. This work was done under the supervision of the writer and A. R. Henry. Traffic signal units were supplied by the Crouse-Hinds Co.

TRAFFIC SIGNAL AT
DALLAS, TEXAS

Hints that Cut Cost and Time

New Portable Tide Gage for Temporary Use

By G. T. RUDE

Chief, Division of Tides and Currents, U. S. Coast
and Geodetic Survey

THE U. S. Coast and Geodetic Survey has recently developed a small automatic tide gage for the purpose of providing a portable, easily-installed gage which can be used to advantage by hydrographic and tidal parties in the field at stations where it is necessary to obtain observations extending over only a few days or weeks for the reduction to a datum plane of soundings taken during a hydrographic survey, or for comparison of short series with long-period tidal observations obtained at principal tidal stations of the Survey. In designing this instrument, the main objects sought were ease of installation and minimum size, commensurate with the desired accuracy in the resulting record of the rise and fall of the tides.

General Description—The essential features of the gage are its small size, its single drum (b) in the illustration—on which the paper record is fastened by means of a spring clip, a single clock movement installed within the drum, a cast base with sleeve (c) to fit on top of a float tube of stock 3½-in. iron pipe (d). This pipe, in addition to serving as a float well, also acts as a support for the instrument, thus obviating the necessity of providing elaborate platform and cumbersome float well. This feature alone renders the gage more adaptable for use by field parties, particularly in remote localities where wharves and docks are not available. Another departure from the usual design of automatic gage is the use of a spring counterpoise instead of counterpoise weights for taking up the slack of the float wire on a rising tide.

The gage is 10 in. square on the base and, with its weatherproof metal cover in place, is 10 in. high. The gage base locks by means of two hook screws (e) into the top section of the float well. This top section (d) of the float well is furnished with the instrument; the remainder of the well, since it is stock pipe, may be purchased in the field from local dealers. The weatherproof cover is locked in place by two padlocks, so that the mechanism is completely covered and cannot be tampered with when the gage is installed in exposed places.

Recording Device—The drum on which the paper record is wound is a single cylinder 7 in. long and 19.2 in. in circumference. This drum is geared to a clock movement carried within the drum, so as to rotate once in 48 hours, giving a time co-ordinate of 0.4 in. to the hour. Upon clamping the milled-nut (a), the drum may be freely turned and the pencil set on the cross-section marigraph paper to the nearest ten minutes of the time co-ordinate of this specially printed cross-

From Job and Office

For Contractor and Engineer

section paper. A tangent screw (added after photograph was taken) on the pencil arm (*m*) permits of setting the pencil to the nearest minute.

The tidal graph is made on a special cross-section paper furnished with the gage. The record paper is wrapped around the cylinder and held in place by a metal clip, running lengthwise of the drum. The use of five different scales of cross-section paper permits the reproduction of tidal graphs to five reduced scales, allowing, therefore, for the accommodation to suitable scales of ranges of tide from 0 to 25 ft. The scales as printed for this gage are as follows:

1:11½	for a maximum tide of	6 ft.
1:16½	" " " "	9½ ft.
1:22½	" " " "	12½ ft.
1:30	" " " "	17 ft.
1:45	" " " "	25 ft.

The change from one scale to another is accomplished by changing the relation between the upper and lower gear wheels (*gg*), the middle one (*h*) being an idler

PORTABLE AUTOMATIC TIDE GAGE

gear. Several sets of these gear wheels are furnished with each instrument.

The pencil screw—(*f*), made of phosphor bronze is connected to the axle of the float pulley (*l*) by means of two gear wheels (*gg*) and an idler gear wheel (*h*).

For adjusting the pencil, when installing the gage, to the height of the tide as read on a fixed graduated tide staff, the milled nut (*k*), holding the upper gear wheel to the pencil screw, is unclamped and the pencil screw then turned freely without connection to the float pulley until the pencil point indicates on the cross-section paper record the height of the tide at that particular time on the graduated fixed staff. This milled nut is then clamped and the penciled curve

will thereafter indicate on the record the reading at any instant of the water level on the fixed tide staff as the tide rises and falls.

The clock is an ordinary eight-day movement, mounted within the drum (*b*) which carries the paper record. The gage, when properly adjusted, will operate for eight days without attention in the meantime. The drum turns once in two days; and, since the lunar and solar days are of different lengths, the tidal curve advances sufficiently from one turn of the drum to the next to obviate any interference of the curve for one day with that of the second day following.

Counterpoise Spring and Float—Instead of employing the usual counterpoise weight for taking up the slack of the float wire on a rising tide, a coiled flat spring 18 ft. long, is used. This spring is coiled within the case of the float wire pulley (*l*), one end fastened to the inside of the outer periphery of the metal case, the other end fastened to a separate extension of the pulley axle. This subsidiary axle, extending from the float pulley (*l*) in a direction opposite to the gear wheels, is controlled by a ratchet and pawl, so that any desired tension may be put on the spring.

The float, a hollow brass cylinder 3½ in. in diameter and 15 in. long, connects the water level to the mechanism by means of a phosphor bronze wire. This float is weighted with shot to float in kerosene oil with its upper end ½ in. above the surface, the oil preventing freezing of the water in the float well in winter. The weight of the float and shot is sufficient to wind the counterpoise spring on a falling tide and at the same time to actuate the recording pencil uniformly.

The float pipe consists of a section, or sections, of ordinary stock galvanized 3½-in. iron pipe. A special bronze base-casting is furnished with the gage, having an inverted cone cast inside. A ¼-in. or a ⅜-in. hole drilled at the bottom of this inverted cone allows ingress and egress of the tide to the float well.

When it is necessary to install the gage in a place at which no wharf or platform is available and to have the float pipe carry the weight of the gage as a standard, another length of pipe is screwed into this cone casting on its bottom end and perforated with a number of large holes to allow free access of the water.

Records Which Should be Kept at a water-works plant should show all facts relating to the operation of the plant—not merely financial items but also an inventory of plant equipment, a record of the amount of water furnished to the distribution system each day, amount of power used per plans of the distribution system, all changes in the distribution system, installation and removal of meters, meter testing, quantities of chemicals used for treatment, data concerning treatment and the results of the examination of all samples of water which are analyzed to determine the quality. The records should enable the superintendent to operate the water-works plant in the most efficient manner. If the plant is not operated continuously a study of the operating records should show at what times and for how long a period the plant can be most economically run. Variations in quantity of water available at the source of supply and the variation in ordinary demand together with the effect of fire demand should be shown, as well as the effect of the seasons both on the quantity and quality of water and on the plant and distribution system. Some old operators know these things but such information cannot be as reliable as the written record, and the new man coming onto the job does not inherit his predecessor's memory.—*Prof. Earle L. Waterman at Iowa Section Meeting, American Water Works Association.*

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Should Swimming Pools Be Emptied in Winter?

Sir—We would like to know the best practice of leaving a concrete swimming pool during the winter in this vicinity where the frost strikes into the ground to a depth of 4 to 5 ft.; that is, should the tank be left full of water, so that expansion of the ice will counteract the expansion of the surrounding earth, or is it considered better to leave the tank empty during the winter season?

ADAMS & RUXTON CONSTRUCTION CO.

Springfield, Mass.,
Nov. 10, 1923.

[So far as our experience goes pools are always emptied in winter, but if there is experience to the contrary we would be glad to put it on record.—EDITOR.]

"What Is the Matter With Reclamation?"

Sir—To the reclamation settlers the reply to the editorial query, "What Is the Matter with Reclamation," raised in your issue of Oct. 25, p. 665, seems a very simple one. After 21 years there is not a project upon which the construction debts, first crediting all payments which have been made, are not greater than they were before payments began, or when original contracts were made. Always under the same direction and control, the settlers have steadily sunk farther and farther in debt, in spite of payments.

To them the basic problem seems to be not engineering, not political, although related to and complicated by both engineering and politics, but strictly economic. How shall reclamation pay out?

In other words the reclamation settler is in very much the same condition, in contrast to the average farmer, which the little boy complained of to his mother—"Ma, these pants are tighter than my skin." Nonsense, Johnny, there's nothing tighter than your skin." "Yes, Ma, these pants are, I can sit down in my skin, but I can't sit down in these pants!" Our reclamation clothes don't fit us. They were built by engineers and politicians according to preconceived theory and the general opinion seems to be that we were made wrong and must be altered to fit them. If we lose a toe or finger, arm or leg in the process or have rather frequent funerals, that is only what is naturally to be expected and should not cause protest, or repudiation of what we never were consulted about, because the Civil Service Commission and the American Society of Civil Engineers have O.K'd the architects and approved the patterns, and the only other side of the question is politics!

We have the right, as one distinguished engineer stated briefly and emphatically a few years since, "only to pray and pay." If we criticize, we will start against us "the influence of the most powerful engineering organization in the world." Is this true?

Reclamation settlers have seldom been able to feel that the engineers in the service as a class and as an organization take a human, or often even a humane, interest in our personal problems and welfare. Due chiefly to this fact we feel they are not properly qualified to direct to ultimate success a problem so complicated with the human element as reclamation, in contrast to strict engineering. This feeling seems to be justified both by the condition of the reclamation fund and by the present trend of the discussion of the problem by engineering societies and journals; as if the technical and not the human factor is paramount, and entirely ignoring the settlers' wishes or opinions.

It is on the human and economic side that reclamation is failing, so that the fund has ceased to revolve, and it is upon this ground that Secretary Work's action must be studied and sustained or condemned.

The very able series of articles upon reclamation now running in *Engineering News-Record* will fail to properly enlighten your readers to answer your own question unless you also present the settlers' viewpoint.

Carlsbad, N. M. Nov. 15, 1923.

FRANCIS G. TRACY,
President, Pecos Water Users' Association.

Effect of Curing Methods on Concrete Roads

Sir—In *Engineering News-Record*, Sept. 20, p. 466, there appeared an article on "Effect of Curing Methods on Concrete Roads" by H. J. Kuelling, construction engineer of the Wisconsin Highway Commission. This article is an instructive and valuable one but I do not believe the results of tests reported warrant the conclusions drawn.

This is especially so in the following paragraph of the report: "In both the field-made and laboratory specimens cured by calcium chloride, the modulus of rupture dropped considerably at 21 days. Because of this rather startling defect some studied consideration should be made before the acceptance of this material as a curing agent."

From the table of this report, which is on page 467, you may observe that in the field specimens cured by calcium chloride the modulus of rupture decreases from 686 lb. per square inch at 14 days to 623 lb. per square inch at 21 days, or 9 per cent in seven days. In the same table under Hay Covered (Field Specimens) the record shows the modulus of rupture decreases from 418 lb. per square inch at 20 days to 333 lb. per square inch at 21 days, or 20 per cent in one day. Still further under Straw Covered (Field Specimens) the results show an increase in modulus of rupture in one day from 420 lb. per square inch to 505 lb. per square inch, or 17 per cent increase. Such losses and gains in strength for one day are absurd. These figures are only given to show the non-uniformity of the strength tests of the concrete after receiving an initial wear test. I do not consider that one should draw conclusions to the extent of condemning a curing agent that shows a 9 per cent variation in strength in seven days when in the same table an approved curing agent shows 20 per cent variation in strength in one day. Furthermore the strength tests in this investigation can be classed only as secondary tests as the modulus of rupture specimens had previously been tested for wear. Therefore, the wear tests are the primary tests. The results of calcium chloride cured field specimens in this primary test show that there is an increased resistance to abrasion between 14 and 21 days. The Calcium Chloride (Laboratory Specimens) show contradictory results, but again collectively showing less wear in time.

A further criticism of this investigation and the extent of conclusions drawn is the lack of a sufficient number of specimens and the failure of rechecking tests. Only three specimens were averaged for each value given in the table and no rechecking of field or laboratory methods is noted.

The Illinois Division of Highways has tested to date over 900 specimens cured by calcium chloride and has not noted any retrogression in strength. Eight hundred of these specimens have been tested for modulus of rupture strength.

Springfield, Ill.

Oct. 23, 1923.

H. F. CLEMMER,
Engineer of Materials,
Illinois Division of Highways.

[Copy of the preceding communication was forwarded to Mr. Kuelling whose reply follows.]

Sir—The writer realizes that the number of specimens covered in the table was more or less limited, but the fact that in every case the calcium chloride specimens showed a decrease, both as to modulus of rupture and as to compression, is, in his judgment, a danger sign and worthy of consideration.

In contradiction to Mr. Clemmer, it should be borne in mind that the cylinders were not subjected to abrasions before compression and are true results. His criticism of

the abrasion tests on the slabs is true, but nevertheless they are comparative as all specimens were subjected to the same treatment.

His criticism of the change in strength over one day periods is, of course, just, but the writer still believes that the results warrant the conclusions as given.

Madison, Wis.,
Nov. 8, 1923.

H. J. KUELLING,
Construction Engineer,
Wisconsin Highway Commission.

Dealers' Profits on Cement to Large Users

Sir—Referring to Mr. Cormack's letter in your Oct. 25 issue, p. 592, defending the cement supply man, it is astounding to find how little even those who are employed to look after the interests of so great an organization as "The National Builders Supply Association," and others intimately associated with the marketing of cement, really know—or rather profess to know—about the ramifications of the business which they are guiding and counseling.

Mr. Cormack intimates that I am quoting ancient history in the incident I mention bearing on the "spread" between the mill and the consumer. I beg to assure him that in September of 1923 I was quoted cement by two reputable dealers at a price 76c. per barrel higher than I had been paying for it for county use—buying through the regular channels—and that on the same day rather than lose the business these dealers met the price I demanded, and one of them conceded another 10c. per barrel when he found that I was willing to go to the plant for the cement. There was no difference to me as to whether I took the cement from a car or from the mill, and 10c. per barrel was worth saving. So Neosho County—hat in hand—and with the dealer's order, went to the plant and secured her cement—and paid her tribute. But she had saved from the rapacity of members of the National Builders Supply Association the tidy little sum of \$324 on a mere bagatelle of 400 bbl. of cement.

No one expects these men to do business with the county or any other unit or individual at a loss; they are entitled to a living profit from their business, and no one suspects that they lost any money in the above named transaction; on the other hand they made as they were entitled to make a reasonable profit.

If it is argued that their prices were based on warehouse delivery, I might answer that we are able to unload and store our cement, hauling one mile from side track to our storage at a cost of 6c. per barrel.

That the cement dealer is a necessary factor I freely admit, and for the small consumer he is indispensable. But my letter in your issue of Oct. 4, p. 567, was a plea for the recognition of the larger consumer—whose unit is car lots—who takes his cement from the car, pays the cash, and who gives the dealer no concern as to whether any, or how many, barrels will be spoiled in storage before being disposed of. I fail to see, however, just how, as Mr. Cormack claims, the elimination of the local dealer in these larger transactions would add to the cost of cement. We have demonstrated from our own experience that the closer we get to the mill door the lower to us is the cost of our cement. The local dealer lives from the profits of his business, supports his various "associations" out of his profits, and hedges against the possible loss of stock by adding to the margin of his profits. To claim that the elimination of all these factors of retail cost would cause the price of cement to skyrocket, sounds like a fairy tale, or a "bogey man" story told to scare the children into being good. The children, in this case the consumers, have been good a long time, but they are getting to the truth of the bogey man stories.

Now comes Mr. Brobston, vice-president of the Dexter Portland Cement Co. (*Engineering News-Record*, Nov. 1, 1923, p. 730), with his defense of the cement maker, and giving voice to an earnest disclaimer of any knowledge of any "association" which has to do with the marketing of his product, or the fixing of prices, or the naming of conditions under which it will be furnished.

How short is memory! Only a few weeks ago "The

Cement Manufacturers Protective Association," of which Mr. Brobston's concern was a member, was dissolved by Federal Judge Knox, as being inimical to the best interests of the country!

In my letter of Oct. 4 I mentioned a dinner tendered my commissioners and myself by a certain cement producing company, at which there was a full and free discussion of the methods of marketing their product, in which they defended their system of doing business only through the recognized dealer. At the conclusion of that conference the general manager assured us, in the presence of other high officials of the concern, that they would be only too glad to recognize the car lot customer as represented by the counties and cities, but it was a matter in which they could not act alone, it would have to be taken up and worked out through "the association." He had already been to great pains to explain to us just how docile, and harmless and powerless "the association" was, and yet he was afraid to act independently, even in the marketing of his own product!

And in the face of all these outstanding incidents we are solemnly told that no one knows of any association, or agreement, or tacit understanding, or any other such thing which would in any way prejudice the cement producer who chose to market his own product in his own way. The public at large, and the users of cement in particular will believe these statements when they can drive to the mill door and buy their cement without an order from a local, or any other dealer.

If Mr. Cormack, or Mr. Brobston needs to be given names and places substantiating any of the statements I have made, he has but to write me personally, and I will be glad to go into the particulars of multiplied instances which, however, have no place in these columns.

O. T. REECE,
County Engineer, Neosho, County,
Kansas.
Erie, Kansas,
Nov. 6, 1923.

Concrete Crib To Prevent Land Slides

Sir—At Utica, Miss., the Illinois Central is using precast concrete cribbing similar to that described in *Engineering*

CONCRETE CRIB RETAINING WALL AT UTICA, MISS.

News-Record, Nov. 1, p. 718, to protect against the sliding of the 25-ft.-high hill on either side of the track.

The accompanying view shows a part of the cribbing in place. This design does away with the row of stretchers on the back side of the cribbing, only the headers running back into the hill. However, the cribbing is given a batter of 3:12 instead of 1:12 as in the Rock Island design.

The Illinois Central requires a concrete foundation for the cribbing. On the Utica cut this consists of a curb one foot wide, top even with the base of rail, and deep enough to rest on rock or good foundation material. With this arrangement it is possible to hold the cribbing to perfect alignment and elevation with no danger of any of the sections settling.

Utica, Miss., Nov. 6, 1923.

KENNETH L. DEBLOIS.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

On Dec. 4, the Civil Service Commissioners of Colorado, will hold an examination for the purpose of selecting an engineer to fill the position of railway and hydraulic engineer for the state public utilities commission, the place made vacant when C. D. Vail left it to become manager of parks and safety for the city of Denver.

Reports that the Pennsylvania R.R. plans to electrify a portion of its system over the Allegheny Mountains, quoted in our last week's issue, is not confirmed. The chief engineer states that no recent consideration has been given to this subject.

A Chair of Transportation Has Been established at Yale University in honor of the late Thomas de Witt Cuyler. This action was taken by the Association of Railway Executives at the recent meeting of the American Railway Association. The chair is to be maintained by voluntary subscriptions from individual railroads.

The National Executive Committee of Stevens Institute of Technology, the nation's first college of mechanical engineering, announces that the pledges of the first week of their world-wide campaign for a million-dollar endowment total \$200,460. This amount includes a contingent gift of \$100,000 from Edward S. Harkness.

Cook County (Ill.) Civil Service Commission will hold examinations Dec. 6, 7, and 8 for civil engineering positions as follows: Inspectors, salary \$200, and junior civil engineers, salary, \$240. The positions are open to residents of Cook County only. About 35 inspectors and 15 engineers are required, largely to fill positions occupied by temporary appointees.

The Cascade Power Co. Has Filed a "declaration of intention" with the Federal Power Commission for a 17,000-hp. development on the Cowlitz River at a point between Portland and Seattle. The project involves the construction of a dam, tunnel and a pipe line. The power will be used for the manufacture of pulp. While the mouth of the Cowlitz River is navigable this development will not come under the jurisdiction of the Federal Power Commission unless it can be shown that it will affect the navigability of the stream.

Virginia's Highway Program Will be much curtailed, it is believed, as a result of the defeat recently of the proposed bond issue. An analysis of the situation since the election indicates that the pay-as-you-go advocates have overestimated the revenue which will come from a three-cent tax on gasoline and one mill on general property. It is believed that the aggregate of the revenue from those two sources will be sufficient only to match federal-aid funds.

Greene to Reduce Personnel in Canal Bureau

According to an announcement made last week Col. Frederick Stuart Greene, state commissioner of public works, has decided upon a reorganization in the Bureau of Canals whereby 100 of the 949 employees are to be dropped from the payroll. By this change Col. Greene hopes to save the state \$100,000 yearly, the present payroll of the bureau now being \$1,335,852. In the new consolidated Department of Public Works, Col. Greene plans to save the state at least \$200,000 a year, the saving being effected in reduction in rents, salaries, and traveling expenses.

County Liable for Bridge Failure

In a decision filed recently by the Supreme Court, Washington State, Cowlitz County is held liable for damages resulting from the collapse of the Kelso bridge last January, with a heavy loss of life (*Engineering News-Record*, Jan. 11, p. 88; Jan. 25, p. 134). The Supreme Court reverses the decision of Superior Judge Reynolds of the Cowlitz County Court, who dismissed the action, and remands the case for trial.

Cowlitz County contended that the Kelso bridge was solely within the city limits of Kelso and that the county had no jurisdiction over it. The Supreme Court opinion asserts that records show the county and city bought the bridge together from a private holder, and that the county has exercised control over the bridge since its purchase.

Rivers and Harbors Congress to Be Held Dec. 5-6

The 19th convention of the Rivers and Harbors Congress is to be held in Washington, D. C., Dec. 5 and 6. Though work on the program is not yet entirely complete, the following projects are to be discussed: Cape Cod Canal (speaker to be announced); Port of Los Angeles, John D. Fredericks, Congressman of California; Port of Hampton Roads, Mayor Albert H. Roper, Norfolk; Intracoastal Waterway, C. S. E. Holland, Houston, Tex.; Pittsburgh's three rivers and their connection with Lake Erie, W. H. Stevenson, Pittsburgh. Other speakers will make brief addresses on the various routes proposed for a canal connecting Lake Erie and the Ohio River.

An interesting feature of the convention will be a discussion on the diversion of water through the Chicago sanitary canal and its effect upon the levels of the Great Lakes. Other features will be the Panama Canal, levees and navigation, shallow water assets, and co-ordination of rail and water transportation. The speakers on these subjects include Senator Ransdell, of Louisiana, and Representative W. J. Driver, of Arkansas.

Many Topics Presented at A.S.M.I. Convention

Paving, Sewage and Garbage Disposal, Water Supply, Street Lighting, City Planning Reviewed

Engineering News-Record Staff Report

Including guests from outside the meeting place about 250 persons attended the 29th convention of the American Society for Municipal Improvements, held in Atlanta, Ga., Nov. 12 to 16. As usual, the program was crowded, but there was more time for discussion than usual. Nearly the whole field of municipal engineering, including city planning and street lighting, was surveyed. Four specifications were passed to letter ballot.

President Horner's Address—The advantages that would result from having a full-time secretary was one of the first things mentioned in the presidential address of W. W. Horner, chief engineer, sewers and streets, St. Louis, Mo. Other suggestions made by Mr. Horner were that the committees of the society might go beyond the standardization of specifications and make reports on the merits of new materials; that more attention might be given to contract forms; and that methods of financing local improvements, the cost of which is met by assessments for benefits could well be taken up. It sometimes happens, said Mr. Horner, that the cost of contract work for local improvement is increased 30 per cent because the contractor has to accept tax liens in payment. Co-operation between the A.S.M.I., the Investment Bankers' Association, and the Associated General Contractors was proposed by Mr. Horner.

OFFICERS REPORT

On motion of T. C. Hutton, it was voted to appoint a committee of three to co-operate with like committees from the Am. Soc. C.E. and from the Sanitary Engineering Section of the A.P.H.A. in obtaining American representation at the International Sanitary Engineering Congress to be held in London next June in connection with the Empire Exhibition.

Reports of Officers—The Executive Committee recommended that the Society endorse the reduction in paving brick and in asphalt standards agreed to by the Simplified Practice Committee of the Department of Commerce and the manufacturers. This was done through the adoption of the report of the Executive Committee. The report of the secretary, C. C. Brown, city engineer, Lakeland, Fla., showed a net membership gain of fourteen for the thirteen months ended Oct. 1, and a total membership on that date of 677, of which 521 are active, 30 affiliates and 126 associates. The debt of the society was reduced by half during the 13 months ended Oct. 1, \$200 being paid from ordinary receipts and \$500 from the sale of Liberty Bonds. The

time and place of the next convention was referred to the Executive Committee, in accordance with a proposed amendment to the constitution which it was voted to send the letter ballot.

New Officers—Ellis R. Dutton, assistant city engineer, Minneapolis, was elected president for 1923-4. Vice-presidents elected are: E. L. Dalton, Dallas, Tex.; T. C. Hatton, Milwaukee; and C. A. Poole, city engineer, Rochester. C. C. Brown, Lakeland, Fla., and Robert Hoffman, Cleveland, Ohio, were re-elected secretary and treasurer, respectively.

Reports of Standing Committees—The Committee on Public Safety, Alcide Chausse, Montreal, chairman, is at work on a building code. The committee, aware of the studies of this subject being made by the Department of Commerce, is giving particular attention to the logical arrangement of a code. The Committee on Public Welfare through its chairman, J. C. Grinnalds, zoning consultant, Baltimore, is giving particular attention to markets, baths and comfort stations. A study of public markets at Baltimore has convinced the committee (1) that stalls should be rented to the users of the stalls only, and that as a rule public markets should be located on the outskirts rather than at the center of the city. H. F. Bascom, a member of the committee, submitted a report on baths and on comfort stations. The latter are more necessary than ever since the eighteenth amendment has closed so many saloons.

FULLER MAKES REPORT

George W. Fuller, for the Committee on Water Supply, sent a report reviewing the committee work of the A.W.W.A. and outlining current waterworks activities in other fields. The Committee on Street Lighting, through its chairman, Ralph Toensfeldt, Engineering Division of Lighting, St. Louis, Mo., laid stress upon the new system of a symmetrical lighting. E. R. Conant, chairman Committee on Street Paving and Street Design, presented a lengthy report which will be abstracted in a later issue.

Specifications Passed to Letter Ballot—Out of a large number of specification committees listed on the program, most either made no report or else merely suggested slight changes. Four specifications, which had been before the association in printed form for some time, were sent to letter ballot: asphalt, stone block, street railway pavement and track construction, and sewers. From the latter, a proposed form of contract was withdrawn in order that it might be made as nearly uniform as possible with other standard contracts to be taken up in the future.

The program called for reports from representatives on committees of other societies. Two or three made program reports and the others did not respond.

Moving Pictures—Films to illustrate how Bridgeport, Conn., salvages worn-out pavements were presented by Charles E. Murphy, of the Texas Co., New York City. Some 140,000 sq. yds. of old macadam was scarified, re-graded, top dressed with broken stone and treated with asphalt by the penetration method in 140 working days by using, successively, four gangs of men and machines. Five reels called the "Story of Fire-Clay Refractories"

South Street Bridge Opened

The city-built bascule bridge over the Schuylkill River in Philadelphia at South St., was officially opened to traffic Nov. 9. The main structure was completed about a month ago, and the approaches have now been finished. The American Bridge Co. was the contractor, and the work was done under supervision of the Bureau of Surveys.

New Chicago Terminal Project

A new terminal station fronting on Van Buren St. and extending between LaSalle and Wells Sts., Chicago, is proposed by the New York Central R.R. as a substitute for the LaSalle Station (one block north of the proposed site), the Dearborn Station and the Grand Central Station. But the Chicago & Western Indiana R.R. already has plans for a new Dearborn Station to replace the same three existing stations, and the Baltimore & Ohio R.R. is understood to have similar plans for combining all the facilities in a new Grand Central Station (see *Engineering News-Record*, Feb. 22 and March 8, pp. 354 and 453). Negotiations between the several railroads and between the railroads and the city will have to determine which one, if any, of the three rival projects should be carried out.

Steel Bridge to Replace Burned Springfield Structure

The joint committee for Springfield and West Springfield, Mass., on the construction of a new bridge across the Connecticut River to replace the North End Bridge destroyed by fire last September has unanimously decided in favor of an open-deck steel bridge, 1,135 ft. long and 70 ft. wide, estimated to cost \$873,000. The J. A. L. Waddell Co., engineers, submitted alternative plans for steel and concrete structures, and the steel bridge was preferred on the score of cost and expedition in building. It is estimated that the bridge can be made ready for use in six or eight months, but this is conditional on prompt approval of the plans by the War Department and necessary legislation by Congress and the Legislature.

Part of the bridge is to rest on the old piers, and the contract will require that that portion, 18 to 20 ft. wide be built first. The roadway will be 54 ft. wide, with an 8-ft. sidewalk on each side. It is proposed to improve the architectural effect with pylons.

Estimates call for \$56,000 for electric railway tracks, including metal to carry the rail base, of which the Springfield Street Railway Co. will be called upon to pay about \$25,000. They also call for \$38,000 to be expended for ducts, this to be borne by the telephone, gas and electric light companies. These items, totalling \$63,000, are in addition to the estimated cost of the bridge.

It is hoped that the contract for the bridge may be let by Feb. 1.

were shown. These were the joint production of the U. S. Bureau of Mines and the Laclede-Stacy Co., St. Louis. Moving pictures were used to illustrate papers on street lighting by L. A. S. Wood, of the Westinghouse Electric & Manufacturing Co., South Bend, Ind., and S. C. Rogers, of the General Electric Co., West Lynn, Mass.

Bascule Counterweight Falls; Drops Bridge

Counterweight Hanger Members Break While Bridge Is Being Closed—New Structure Planned

A 65-ft. highway bascule bridge over the Lachine Canal, at Ville St. Pierre, near Montreal, failed on Oct. 3 by the breaking of the counterweight hanger members, which dropped the counterweight and the bridge span. The accident occurred while the bridge was being closed. When the free end of the span was yet 20 ft. above the abutment the rear hanger at the upstream side of the counterweight broke through just inside the concrete. The downstream rear hanger then broke and the counterweight swung forward on the two forward hanger members, breaking off one of them and shearing the rivets at the other one. The span fell from a height of about 7 ft. above the abutment. The bridge was built in 1912 by the Dominion Bridge Co. to designs by the Strauss Bascule Bridge Co.

To clear the canal for traffic, the operating link connecting the forward end of the counterweight walking-beam with the top chord of the bridge was cut near its lower end by torches, and the heel pins of the span were withdrawn, permitting the span to be lifted and rolled out of the way longitudinally.

No information about the accident has been obtainable from the Canadian Department of Railways and Canals (W. A. Bowden, Ottawa, chief engineer).

STRAUSS COMPANY ISSUES STATEMENT

The Strauss Bascule Bridge Co. says: "The Lachine Canal bridge was one of the earliest heel trunnion bridges built, having been designed in 1911 while the first of the type was completed in 1910. There existed no specification for bascule bridges such as have now been developed based on experience, and we had not yet developed that perfect co-operation with the fabricator that now obtains. In the early bridges of heel trunnion type steel plates were used for partial support of the counterweight, these plates covering the two entire side surfaces of the counterweight. This detail was long ago abandoned and replaced by embedded members.

"Some five or six years ago these plates were removed from the Lachine Canal bridge without the co-operation of all parties interested and without due regard to the function performed in taking part of the stress involved in the support of counterweight. The result, evidently, was to overload the remaining members connecting the counterweight to the counterweight trusses. In spite of this only half of one of the embedded members failed initially, the character of the fracture showing that this failure was one of long standing and evidencing that the bridge continued to operate even with the overstressed member.

"The Department of Railways and Canals has authorized us to prepare plans for placing the bridge back in service, and we are building into the counterweight our later details, which fully provide for secondary stresses and for reversal of stresses and similar considerations, knowledge of which grew out of our experience with these early designs. The heel trunnion type has now been reduced to standardized design in both theory and practice."

U. S. Chamber Reports On Transportation

Recommendations Made Based on
Theory Best Service Is Possible
Only Through Co-operation

After a careful study of the recent developments in the transportation situation of this country caused by the great increase in the use of motor transport on paved highways, the Committee on the Relation of Highways and Motor Transport to Other Transportation Agencies of the Chamber of Commerce of the United States has come to the following conclusions:

1. The best interests of the public and the rail, water and motor carriers lie in the co-operation between the various agencies of transportation rather than in wasteful competition; 2, the greatest opportunity for co-operation is at the point where the capacity of the railroads is most limited and expansion is difficult and costly; that is, in the terminal areas of our great cities; 3, store-door delivery by motor transport is the greatest contribution which can be made to the solution of the terminal problem; 4, organized motor transport can also relieve the railroad from various forms of uneconomical service, such as switching between local stations and short-haul shipments within the terminal area;

5. To secure the fullest benefit from this organized motor transport will require the utilization and further development of modern technical equipment, such as demountable bodies, trailers, container cars and mechanical handling appliances; 6, outside of the terminal areas there are distance zones in which one type of carrier, the motor for short haul and the railway or waterway for long haul, is clearly more economical than the other, and intermediate zones in which competition is inevitable; 7, it is to the interest of the public and the carriers that the economic limitations of each type of carrier be recognized, that the railroad be permitted to discontinue unprofitable service to which the motor is better suited, and that the motor abandon its efforts to handle general traffic over excessive distances; 8, to insure to the public continuity and reliability of service, sound financial organization of motor transport is necessary as is public regulation of common-carrier motor service; 9, passenger bus transport should be so regulated as to secure the best service to the public (rail lines can often advantageously extend or supplement their service by bus lines, and any restrictions against such service should be abolished);

10. Regulation of traffic and of size, weight and speed of motor vehicles should be made more uniform within states and the regulation of common carrier operation of motor vehicles, including rate regulation, should be handled by federal or state authorities, under the commissions which now control the operation of rail and water carriers; 11, truck highways in any area should be able to carry the normal vehicular traffic of that area, and, if the traffic economically justifies the use of specially heavy trucks, highways with stronger substations should be provided; and 12, investigations now under way by the U. S. Bureau of Public Roads state and highway departments and other agencies to de-

A. P. Davis Is Honored By Washington Engineers

Arthur P. Davis, the past president of the American Society of Civil Engineers, who was summarily dismissed as Director of the Reclamation Service by Secretary Work, has been elected to honorary membership by the Washington Society of Engineers. This honor has been conferred on only four others. They are: Commerce Secretary Hoover, Admiral H. T. Endicott, Admiral D. W. Taylor, and Dr. F. H. Newell. Mr. Davis now is in England, representing the Department of State on engineering matters coming before the Pecuniary Claims Commission.

River Terminal for Cincinnati

A steamer dock on the Ohio River front with warehouse, railway connections and freight-handling equipment is to be built by the Cincinnati River-Rail Transfer Co., and it is expected to have this terminal in operation early in the spring of 1924. The purpose is to provide more efficient and economical handling of river-borne freight than is practicable with the old arrangement of a levee and wharf boats. The company was organized partly as a civic enterprise, backed by the Chamber of Commerce, charges to be regulated by the city and a fee paid to the city for each ton handled or for each vessel. J. A. Pollak, of the Pollak Steel Co., is president; Major Bert L. Baldwin is chief engineer.

Arizona Governor Fails to Extend Girand State License

Washington Correspondence

The governor of Arizona has declined to extend the time of the state license covering the Girand development at Diamond Creek on the Colorado River. Mr. Girand has filed the governor's letter with the Federal Power Commission.

This puts it squarely up to the Federal Power Commission to take action in this case which involves a \$90,000,000 transaction. If the Commission refuses to take action before Dec. 26 on the Girand license, it will mean, unless the governor reverses himself, that the Arizona copper companies would no longer be committed and might decide to rely for a longer period on fuel oil. The decision to resort to hydro-electric power was made at a time when the prospect for securing adequate supplies of fuel oil at reasonable prices was not as good as it is at present. Arizona would be the greatest sufferer were the scheme to fall through. For that reason, some are of the opinion that the state executive may change his mind as soon as he is sure the Federal Commission will not grant the Girand license before Dec. 26.

On the other hand, the Federal Commission must face a heavy moral, and possibly a legal responsibility, if through failure to grant a license, Mr. Girand, who has complied with all the conditions of the preliminary permit, should be subjected to great losses.

termine more fully the economic role of the motor vehicle, should be continued.

Federal Power Commission Issues Third Report

Plea Made For Settled Public Policy
To Have Uniform Application
In All States

Appreciating the desirability of common action in matters of hydro-electric development, the Federal Power Commission, in its third annual report, just made, makes a plea for a settled public policy which will have uniform application in all the states. Only by such a policy can the country be assured of a systematic development of its potential power possibilities into a great interconnected system without expensive reconstruction or unnecessary duplication. The commission advises that legislation which interferes with such a program should be repealed or modified, nor should it be permissible for any utility to draw plans for future extensions except in such manner that interconnections may be effected when feasible.

The commission points out that the ownership and control of water powers by public agencies should be made a policy of all the states as it now is a fundamental policy of federal water-power control. It also emphasizes the fact that values inherent in a public resource developed and used in the performance of an essential public service shall not be capitalized in excess of amount actually expended in acquisition. This policy is being carried out by the commission as far as all sites under its control are concerned, and these sites involve 85 per cent of the total water powers of the United States. If this principle is applied by the states to all structures and equipment erected or used on the site as well as to the power itself, the commission sees simplification of rate adjustment. Public regulation of rates has not been an entire success largely through the fact that public service commissioners have been chosen for their political affiliations only.

FUNDS AND PERSONNEL LACKING

The commission is now hampered by the lack of sufficient personnel and funds to carry on its work properly. At the present time its personnel is made up of the three departments part of whose work still has to do with the administration of permits issued under the provisions of earlier laws. The commission recommends that the act be modified so that the administration of all projects will come under the Federal Power Commission. Such a change would make available certain funds which other departments of the government are now using for water power investigations which largely duplicate work required by the Federal Power Commission when issuing permits for such projects. The commission lacks an adequate accounting department needed to control accounts in order that they are not padded with capital not actually put into the development.

The Water Power Act provided that the annual license charges should make the commission independent of support from the Treasury, but the greater part of such funds either are not yet available or are absorbed by prior liens upon them. The commission recommends that the act be amended to make these funds available for its use in order that it may obtain sufficient personnel and still be a self-supporting branch of the government.

Progress on Mississippi Freight Service

Colonel Ashburn's Report Mainly An Essay on Essentials of River Freight Transportation

Col. T. Q. Ashburn, Coast Artillery Corps, U. S. A., and chief of the Inland and Coastwise Waterway Service, has just rendered his annual report on the operations of that service, which has charge of the government fleet on the lower Mississippi and the Warrior Rivers. The report is mainly an essay on the essentials of river freight transportation and an explanation of the difficulties of freight operation on the lower Mississippi River where the government since early in the war has been trying to maintain an economic freight service.

Col. Ashburn lays down the following conditions precedent to success of any inland waterway service: (1) A suitable navigable waterway; (2) suitably designed equipment for each particular waterway, which equipment must be determined by experiment; (3) suitable terminals and balanced freight both ways; (4) interchange of freight with the railroads; and (5) equitable division of revenues accruing to both water and rail transportation for a combined haul. He said that none of these five essential elements is present on the upper Mississippi, so that it is not practicable at the present time to attempt government or any other freight operation above St. Louis.

CONDITIONS BELOW ST. LOUIS

Below St. Louis conditions are more favorable, but the government operation is difficult because of the lack of certainty on the part of the shipping public as to whether governmental operations may not be suddenly abandoned, the tendency on the part of individuals or communities to bring political pressure to bear upon the operation, and the inability of the government waterway line to finance itself in periods of depression. He, therefore, recommends a semi-public body to conduct the operations of the Mississippi waterway and presents a bill embodying his suggestions. This bill would create a corporation under government control but with private functions, which Col. Ashburn thinks would avoid most of the difficulties of the government operation of the Mississippi waterway.

Col. Ashburn holds that the lower Mississippi operation was successful, although it continues to lose money if the heavy charge of the war-time equipment is carried on the books. The eighteen months ending July, 1923, were particularly hard ones because of the tremendous flood which went down the Mississippi in 1922 and which very seriously affected the operation of any of the barges. The tonnage for the six months preceding the flood was 375,480; for the flood period, 224,206, and for the succeeding six months, 370,909, which, as the Colonel states, tells its own story. The lowest tonnage was due partly to the difficulties of landing and loading at high water, but mainly to the disturbances to the channel caused by the flood.

In figures, the total income on the Mississippi section from Jan. 1, 1922, to July 1, 1923, was \$3,504,512.22. The total operating expenses during the same period were \$3,961,989.47, of

Marginal Belt Line to Be Set Up at Port of New York

The Port of New York Authority has announced that the railroad companies having terminals on the New Jersey side of New York harbor have agreed to allocate certain portions of their properties to be used for the Port Authority's marginal railroad No. 13 and have agreed to spend approximately \$500,000 for the construction of certain railroad connections and signal systems to make such a belt line effective. The railroads have also agreed to appoint a director of operation for this belt line, who will be selected from among the officers of some railroad not directly interested in the property. Equipment will be supplied by the individual roads.

The Port Authority also announces that its engineers and those of the carriers' operating committee are continuing their studies of the outer belt line with the idea of being in a position to start construction of that railroad in the near future in order to relieve the marginal belt line from much of the interchange business which it now handles to the detriment of the switching along the water front.

LaDu Recommends Abandoning Black River Canal

State Engineer and Surveyor Dwight B. LaDu, in his annual report to the New York Legislature will urge the submission to the people of a constitutional amendment permitting the abandonment of the Black River canal which extends from Carthage to Rome. Mr. LaDu's position is that the period of usefulness of this section of the old Erie Canal, which has never been a part of the barge canal, is long past, but two or three boats passing through the canal each year. Mr. LaDu said he would also recommend the abandonment of a strip of the old Erie Canal near Buffalo.

The abandonment of the Black River canal will sound the death knell for another barge canal connection with Lake Ontario via Carthage, Watertown and Sackett Harbor, a project which has been advocated for many years. The nearest this proposal came to materialization was in 1913 when legislation was introduced providing for additional bond issues to the amount of \$22,000,000, part of which was to be expended for a barge canal over this territory, which proposal failed of passage.

which \$432,000 is depreciation. The main loss was, as noted, in the flood period. For the remaining twelve months actual profit was made.

On the Warrior River the losses were "staggering." According to the Colonel's report, this division has been handicapped by the railway opposition, has never had suitable barge equipment or towboat equipment. The average monthly loss on the Warrior River for the fiscal year 1923 was \$54,132. Col. Ashburn estimates that with proper equipment on the Warrior River and with proper rates controlling on the railways, the revenue on the Warrior River would have to average \$2.46 per ton in order for the operation to break even. At present, average figures for 1923 show an average revenue of \$1.68 per ton and an average cost of \$9.95 per ton, leaving a deficit of \$2.27 per ton.

Engineering Employment Shows Slight Recession

Numerous Inquiries Being Received—Civil Engineers Hardest Hit—Los Angeles Permits

Employment conditions affecting engineers reflect considerable irregularity with special divergencies between the trends in different industries and engineering endeavors, but on the whole, engineering employment throughout the country is fair. Numerous inquiries are being received from all sections of the country from men desirous of making new affiliations, or who report the completion of their work, indicating that a slight recession in employment is apparent. These are the observations of E. B. Miller, employment secretary, American Association of Engineers. A fair volume of placements has been accomplished through the Chicago office of the association. The business of October exceeded that of September by 12 per cent. In the latter month there was practically no unemployment among engineers, but during October some unemployment was noticed and it is now increasing slowly. So far, however, most men requiring new positions were able to make connections in a short time which will last at least for the winter months. In the Chicago district more than 300 engineers were laid off during October and early in November 100 engineers had been given notice of discontinuance of their employment during the month.

CIVILS HARDEST HIT

Civil engineers are hit the hardest at this time, particularly those on construction work, including superintendents, instrument and general field engineers. Practically no demand exists for men on irrigation, drainage, hydraulic or construction work. Manufacturing and industrial companies have reduced their technical staffs although a few lines continue actively, such as machinery, tool, railway equipment and automobile manufacturers. The greatest demand is for architectural engineers and draftsmen. A fair demand is evident for highway engineers, especially designers on plans and bridges. The railroad field for engineers is practically dormant. The electrical industry is fair with a good demand for junior men for minor positions and a fair demand for a few electrical technical experts. The chemical and mining fields have not shown any great changes, but not much unemployment is noted in these two lines.

The greatest number of building permits during October for any city, was issued in Los Angeles, exceeding the building permits for Chicago, which so far this year had held first place. Positions for engineers on the Pacific Coast and Southern California are fair. In the Northwest, conditions are tightening with little work for engineers in the states of Washington, Montana and Idaho. The Middle West is fair for employment and men can find something to do if they are willing to accept what is offered. The Eastern section is not very desirable for employment; more men are looking for positions than there are positions open. The South is starting considerable activity with a good demand for engineers of the junior grade. The greatest unemployment at the present time is in the Northwest and Eastern sections of the country.

Random Lines

Animal Magnetism

Sir—There are several different ways of finding the points of the compass, but the following, while it is not a new method, is a new one to me. I have clipped it from "Century Readings in American Literature" published by the Century Co. 1923:

"In 1729, William Boyed was a member of the expedition sent to determine the dividing line between Virginia and North Carolina. In his 'The History of the Dividing Line,' 1841, he writes:

"He told us a Canterbury Tale of a North Briton whose curiosity spurred him a long way into the Great Desert (The Dismal Swamp) as he called it, near twenty years ago, but he having no compass, not seeing the sun for several days together, wandered about till he was almost famished; but at last he bethought himself of a secret his Countrymen make use of to pilot themselves in a dark day.

"He took a fat louse out of his collar, and exposed it to the open day on a piece of white paper which he brought along with him for his journal. The poor insect having no eyelids, turned himself about till he found the darkest part of the heavens, and so made the best of his way toward the North."

C. D. P.

Query? Does The Engineer Need a Broader Education

SIGN ON THE BROADRIPPLE SWIMMING POOL AT INDIANAPOLIS, IND.

The Supply is Getting Low

We think we have about exhausted the supply of adjectival engineers, because our voluntary scouts are beginning to report duplicates. Two new ones have shown up, though, one bona fide, a "dehydration engineer" who advises California farmers how to dry fruits, and one hypothetical, the "psychic engineer," who, a certain professional spiritualist claims, is needed today by the world. This latter brother will "spend his time and life, if need be, to the study of high tension and grasping the messages from the other side of life on this side."

Standardized and Replaceable?

"Engineer To Be Man of Many Parts in Future," says a Cleveland paper in reporting the Carnegie Foundation's new study into engineering education.

Large Power Development Proposed for Columbia River

The Washington Irrigation & Development Co. has applied to the Federal Power Commission for a license covering its development at Priest Rapids on the Columbia River between Spokane and Portland, and has stated in the application that it will start work immediately upon issuance of a license with the idea of having the first lot of power, amounting to about 200,000 hp., ready for delivery within four years. The development as now proposed calls for the construction of a dam partly of concrete and partly of earth fill 2½ miles long. The power house will be built in the dam, the initial section being 660 ft. long, with a provision for a 700-ft. extension. The spillway section will contain 127 gates 30 ft. long with a flood discharge capacity of 1,200,000 sec.-ft., or almost double the amount of the largest flood on record, which is 710,000 sec.-ft. The head to be developed is 70 ft. The initial installation will be six 40,000-kva. and two 29,000-kva. units, and the additional future installations will be ten 40,000-kva. units. The initial installation will cost approximately \$28,000,000 while the project in its final form is expected to represent an outlay of \$41,000,000. The dam will be provided with two navigation locks and a fishway.

George P. Coleman Chief Speaker at Highway Officials Session

Due to the fact that C. J. Bennett, nominal head of the American Association of State Highway Officials, though no longer a highway official, cannot be present at the New Orleans Convention Dec. 3, 4, 5 and 6, the principal address will be delivered by George P. Coleman, of Virginia, the retiring chairman of the Association's executive committee. In that address, Mr. Coleman will review his eleven years' service as a state highway official during which he has been particularly active in connection with federal legislation pertaining to highways.

J. M. Parker, the Governor of Louisiana, and Andrew McShane, the Mayor of New Orleans, will speak at the opening session to welcome the delegates to the Louisiana metropolis.

Arrangements have been made to present during the convention, the new films of the Bureau of Public Roads entitled "Motoring Through Maryland" and "The Changing Road."

In compliance with an invitation from Tulane University and the University of Louisiana, the Association has agreed to arrange with highway engineers to lecture before classes at those universities, during the time that the convention is in session.

Reports will be submitted by the Committee on Standards including subcommittees on plans and surveys, design, specifications, traffic control, bridges and structures; Committee on Administration, and the Committee on Construction.

Besides Mr. Coleman, speakers will be Henry G. Shirley, F. S. Greene, J. H. Mullen, G. W. Hutchinson, Clifford Older and Thomas H. MacDonald.

F. R. White is acting president of the association.

Coal Commission Urges Profits Tax on Coal Operators

The Coal Commission in its latest report on the profits of anthracite coal operators recommends that a profits tax be applied to the operations of the coal mines. It finds that no sweeping horizontal cut can be made in the price of coal at the mine, or in the margins, without serious injury to many high cost operators whose output is needed. The consumer will benefit indirectly through the lightening of taxes elsewhere. In addition the commission again recommends requiring complete publicity of the operators' accounts and urges the public to resort to the use of substitutes in order to protect itself against unreasonable profits.

These recommendations are based on a study of the coal operators' margins, which study shows that these margins range from nothing to over \$2 per ton, and that the per cent return on the book value of the investment ranges all the way from a loss to a return of 138 per cent. The book values have had very large increments in recent years and are largely shrouded in mystery but there is ample evidence of certain "write-up" amounting to at least \$186,000,000 and in addition there were memorandum accounts kept for Federal tax purposes indicating further appreciation of \$40,000,000. These however are 1913 figures and if the valuation of \$989,000,000 placed on the mines and minerals by the commission's engineers are to be taken as correct there will be much greater increases because the owners book valuation is now only \$600,000,000.

The commission finds that the practice of carrying large reserves of coal lands adds to the cost through taxes and conceals profits. The largest of the railroad coal companies, the Philadelphia & Reading, a high operating cost company, has sufficient reserves to last 200 years. On this total investment it has shown an inadequate return, the loss having been made up out of the earnings of the affiliated railroad. The commission calls especial attention to the matter of the increasing value of these reserve coal lands, both for anthracite and bituminous coal, and points out that if it is allowed to continue indefinitely, piling up carrying charges to be added to the current price of coal an intolerable burden will be laid on the consumer. Taxes and interest on coal not to be mined in the next forty years are not properly chargeable to present operations.

St. John Opens New Drydock

The new drydock of the St. John Drydock and Shipbuilding Co. at St. John, N. B., has been opened with a formal ceremony by the governor-general of Canada, Lord Byng. The new dock, according to its owners, is the largest of its kind in the world. Its extreme length is 1,225 ft. and the length on the block is 1,150 ft., and it is so arranged that it can be used as two drydocks, one 650 ft. long and the other 500 ft. long. The patent slipway is 720 ft. long, and the cradle 240 ft. The depth of the sill at high tide is 42 ft. and the draft of the keel block at extreme high tide is 14 ft. The dock is equipped with a 70-ton fixed crane and a 20-ton traveling crane.

Engineering Societies

Calendar

Annual Meetings

AMERICAN ASSOCIATION OF STATE HIGHWAY OFFICIALS, Washington, D. C.: Annual Convention, New Orleans, La., Dec. 3-6, 1923.

FEDERATED AMERICAN ENGINEERING SOCIETIES, Washington, D. C.: Annual Meeting, Washington, D. C., Jan. 10-11, 1924.

AMERICAN ROADBUILDERS' ASSOCIATION, New York City: Annual Convention, Chicago, Jan. 14-18, 1924.

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York City: Annual Meeting, New York, Jan. 16-18, 1924.

ASSOCIATED GENERAL CONTRACTORS OF AMERICA, Washington, D. C.: Annual Meeting, Chicago, Ill., Jan. 21-24, 1924.

AMERICAN CONCRETE INSTITUTE, Detroit, Mich.: Annual Meeting (20th anniversary), Chicago, Ill., Feb. 25-28, 1924.

The Engineering Society of Western Massachusetts at its meeting Nov. 20 in Springfield, Mass., was addressed by Charles E. Wells, consulting civil engineer of North Adams, Mass., on the "History of the Hoosac Tunnel," and by Col. B. A. Franklin, head of the Bridgeport Division of the Ordnance Department, on the subject, "If the United States Were Again Forced to Fight Would She Be Prepared?"

The Engineers' Club of St. Louis discussed the question, "How Engineering Leadership Can Reduce Seasonal Unemployment" at its meeting of Nov. 9, with A. P. Greensfelder, secretary of the Fruin-Colton Contracting Co., St. Louis, and E. A. Hadley, chief engineer of the Missouri Pacific R.R. Co., St. Louis, as the principal speakers.

Personal Notes

MICHAEL C. HINDERLIDER, consulting civil engineer, Denver, Colo., has been appointed state engineer for Colorado to fill the vacancy caused by the resignation of A. J. McCune. Mr. Hinderlider is a native of Indiana and a graduate of Purdue University. He went to Colorado in 1900 and was soon appointed engineer of the Denver Board of Public Works. From 1902 to 1908 he was engineer in charge of hydraulic work for the U. S. Reclamation Service in the Rocky Mountain Division, embracing seven states. Later he was engineer in charge of construction of the hydro-electric power plant at Shoshone Falls, Colo. Since 1909 he has been in private practice and has designed irrigation systems and earth and masonry dams.

DR. D. B. STEINMAN sails Dec. 4 on a four-months' trip to Sydney, Australia, where he will submit plans which he has been retained to prepare, in partnership with Holton D. Robinson, for the \$30,000,000 Sydney harbor bridge.

STEPHEN T. DE LA MATER, chief of the amortization section, income tax unit, Bureau of Internal Revenue, Washington, D. C., has resigned and will return to private practice as consulting engineer with offices in the Insurance Bldg., Washington, D. C., specializing in problems of taxation, operation and valuation as related to construction.

COL. W. J. BARDEN, Corps of Engineers, U. S. Army, was the honor guest and principal speaker at a recent joint meeting of the Seattle Section, American Society of Civil Engineers, and the American Society of Military Engineers at the Engineers Club, Seattle. Col. Barden spoke on "The Muscle Shoals Power Development," of which work he had charge for three years.

DANA PIERCE, first vice-president of Underwriters Laboratories, in charge of the New York office, and an electrical engineer, has been elected president succeeding William H. Merrill, whose death was noted recently in these columns. R. R. SMALL, one of the vice-presidents, has been elected first vice-president.

H. V. KNOUSE, construction engineer, Metropolitan Utilities District, Omaha, Neb., has taken charge temporarily of the operation of the pumping station at Florence, a position held until recently by A. B. Hunt, superintendent. Mr. Hunt, who has been an employee of the water-works for more than forty years, was relieved of the above duties following an investigation by the directors of the district into the responsibility for a deluge of mud which the city experienced in August. Mr. Hunt is still retained on the payroll.

JOSEPH A. MARTIN, former commissioner of public works for the city of Detroit, under whose direction a large part of Detroit's extensive public improvement program including the \$25,000,000 sewer system was carried out, was elected city councilman in Detroit at the Nov. 6 election, and having received the highest number of votes of the nine members elected, will become president of the council.

ELISHA LEE, who is at present vice-president of the eastern region of the Pennsylvania R.R., has been appointed vice-president of the central region, succeeding Col. James A. McCrea, who died Oct. 17. Mr. Lee has been in the service of the Pennsylvania R.R. since 1892. During government control of the railroads he was federal manager of the Pennsylvania lines east of Pittsburgh and prior to that had been general manager.

CHARLES S. KRICK, who succeeds Elisha Lee as vice-president of the eastern region of the Pennsylvania R.R. system, entered the Pennsylvania service in 1887 as a rodman. He has since worked his way up through the positions of general superintendent, assistant general manager and general manager.

ROBERT V. MASSEY succeeds Charles S. Krick as general manager of the eastern region. He entered the Pennsylvania service in 1892 as an engineer in the construction department and later entered the operating department, becoming a superintendent, general superintendent, and then assistant general manager of the eastern region.

F. P. LARMON, chief engineer, Metropolitan Utilities District, Omaha, Neb., in charge of construction of the new filtration plant, tendered his resignation to Col. Theodore A. Leisen on the latter's assumption of the management of the district, as noted in these columns last week.

DR. DOUGLAS W. JOHNSON, since 1901 professor of physiography in Columbia University, has been appointed exchange engineering professor to France and will represent seven American universities—Cornell, Harvard, Johns Hopkins, Massachusetts Institute of Technology, Pennsylvania, Yale and Columbia. He will lecture in all the principal French universities on physiography and its applications. Professor Johnson was chief of the division of boundary geography of the American Peace Commission to France.

Obituary

CHARLES T. HARDING, JR., for the past ten years superintendent of the water-works and the light plant at Pelican Lake, Minn., was drowned in Pelican Lake, Minn., Nov. 1. Previous to 1913 Mr. Harding was associated with the Burns & McDonnell Engineering Co., consulting engineers, Kansas City, Mo.

PERCIVAL WALTER ST. GEORGE, civil engineer, Montreal, died in that city Nov. 12 in his seventy-fourth year. Mr. St. George was born in Scotland and was educated in France and at the University of Edinburgh. He went to Canada in 1866 and for some years was engaged in railroad construction for the Nova Scotia Ry. and Intercolonial Ry. In 1876 he was appointed deputy city surveyor of Montreal and in 1883 became city surveyor, in which position he was noted for his work in flood prevention, drainage and city paving. Since 1900 he had practiced as a consulting engineer. He was one of the original members and a vice-president of the Canadian Society of Civil Engineers.

HORACE R. CARPENTER, assistant chief engineer of the Missouri Pacific R.R., was found dead at the door of his apartment in St. Louis on Nov. 12. Mr. Carpenter, a graduate of Yale, class of 1883, had been with the Missouri Pacific R.R. for eighteen years. Prior to that he served as consulting engineer for various railroads and mining properties. During the world war he was chief engineer for the railroads in Louisiana and Arkansas.

THOMAS R. H. DANIELS, chief civil engineer of the Terre Haute, Indianapolis & Eastern Traction Co., Indianapolis, died of heart disease Nov. 8 after an illness of two days. In 1898 Mr. Daniels was assistant engineer of track and roadway of the Rhode Island Co., Providence, R. I.; and in 1904 became assistant engineer for Westinghouse, Church, Kerr & Co., New York City, in the construction of the new terminal station for the Pennsylvania R.R. Two years later he took charge of the rebuilding of tracks of the United Rys., San Francisco. For some time he was chief engineer for the Birmingham, Ala., Railway, Light and Power Co.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Tardy Orders for Supplies Upset Building Schedules

Manufacturers Cannot Always Satisfy Eleventh-Hour Demands of Engineers

In the Nov. 8 issue of "Engineering News-Record," p. 783, a manufacturer of waterworks equipment deplored the insufficiency of time usually allowed for preparing estimates or bids on proposed work. Manufacturers of other products used in the construction field were asked for a statement of their experience or an expression of their opinion. Some of the replies follow.—EDITOR.

Steel Doors and Partitions

By ERNST DOSCHER
The J. G. Wilson Corp., New York

WE DO not have much cause for complaint because of the shortness of time to submit bids on our products, as it takes but a few moments for us to figure a proposal.

Our chief complaint is that on account of the fact our products (rolling and folding doors and partitions) are about the last things to be installed in a building, contractors delay placing their orders with us until they are almost ready to have the products installed. Our lives are then made miserable by their pounding us for shipping dates.

This is especially true in August and September on school work. Many contractors delay until June or July before they order the partitions and wardrobes that we manufacture and which are required for the opening of schools early in September. This floods our factory with orders and it is impossible to ship in time to meet all demands.

The same thing is true as regards our rolling steel doors used on the exterior of buildings. The contractors wait until the fall before placing their orders and then are in dire need of the doors to protect the building against the weather. We have tried to get them to place their orders well in advance and let us manufacture our products based on sizes which are guaranteed by them, so that there will be no delay when the building has progressed to the point that installation can be made. In this, we are only partly successful.

Cement Tile Roofs

By L. J. WILHARTZ
Federal Cement Tile Co., Chicago

RELATIVE to the period of time generally allowed for the submission of bids on proposed contracts, in a great many instances we could use additional time in the more careful preparation of our bids. In the main, however, we do not feel that we have a legitimate complaint in our particu-

lar line of business. Taking into consideration the pressure under which most business concerns operate today we feel that we are receiving all of the time that we could reasonably ask for.

Water Filters and Softeners

By GEORGE F. HODKINSON
American Water Softener Co.,
Philadelphia

WE HAVE noted and heartily endorse the views expressed by C. G. Richardson in his article appearing in your issue of Nov. 8. In many instances the time allowed between date of advertisement and date set for receiving bids is so short it is impossible for us and many others to bid, and this may exclude some low and desirable tenders.

If ample time is allowed, bidders have an opportunity to shop around for prices which might enable them to bid a lower figure than if compelled to make wild guesses. It is often necessary to visit the site of the work, to become acquainted with local labor and other conditions and to get information from the engineers by correspondence, in order to bid intelligently, and this takes time.

Too much publicity cannot be given to this matter, as a reform is urgently needed.

Reinforced-Concrete Chimneys

By R. A. STEEN
Weber Chimney Co., Chicago

IN OUR line, which is the construction of reinforced-concrete chimneys, probably 50 per cent of the cases offer sufficient time for preparing estimates or bids, which is desirable and which naturally results in a saving to the purchaser if the bidder has an opportunity to check over prices of materials and labor carefully, getting complete data as to working conditions. If in doubt, or if he lacks adequate information to protect himself from contingencies he is compelled to bid higher.

We certainly believe rush preparation of bids results in increased cost. On probably 25 per cent of municipal jobs there is barely sufficient time and on possibly another 25 per cent there is insufficient time to bid properly.

We would call attention to the following practice which we think is not fair to the bidder, although it seems to be coming into vogue: That is the practice of engineers preparing specifications for municipalities and then charging a fee for a copy of the plans and specifications. In some instances a portion of this fee is refunded if the plans are returned, and sometimes not. Of course it is quite proper in some cases to ask for a deposit for plans and specifications, although we think with reputable bidders that this really is unnecessary as the bidder is going to more or less expense in preparing his bid and sending a representative to the letting, and he certainly should not be asked to pay for copies of specifications.

Another hardship on the manufacturer is the unwillingness or failure of municipal authorities to give accurate information to the bidder as to when the actual letting will take place. This practice results in uncertainty and additional expense to the bidders for sending their representatives. In certain instances it is also difficult, after the bids have been considered, to find out who secures the business. Certainly every bidder who puts up his certified check and other necessary expenses should be entitled to full and complete information along these lines.

Fire Doors for Elevator Shafts

By M. L. EDELMAN
The Pella Co., Brooklyn, N. Y.

THE shortness of time generally allowed for the preparation of bids, does not effect us materially since the quantities for our products can be quickly ascertained from plans and specifications, and prices made up within a very short period of time.

Valves and Hydrants

By C. A. ANDERSON
Chapman Valve Manufacturing Co.,
Indian Orchard, Mass.

MR. C. G. RICHARDSON'S comments are well worth consideration. We have noticed in many cases that too short notice is usually allowed to get in quoted prices. Mr. Richardson is quite correct in saying that the people who lay out work sometimes take months and even years to get it lined up, and then expect the contractor to get his prices in within a very short time.

There are many cases requiring special equipment that one manufacturer may not make and has to purchase outside. Often we have been called upon to name prices on short notice and have had to telephone long distances for information from other manufacturers. In doing this we could not, of course, submit complete details or prints of what we had in mind and it was more or less guesswork getting quotations out. Naturally when prices are made on this basis they are usually high and would be termed approximate, and consequently the customer does not receive competitive prices as would be the case if sufficient time had been allowed to go at the matter in a proper way.

Steel Window Walls

By A. T. HOGG
Detroit Steel Products Co., Detroit, Mich.

WE have very little complaint to make about lack of time for preparing bids. I think, however, this may be due to the fact that we have a very efficient estimating organization in each of our branch offices and most of our principal agents also are equipped to give this service locally. For this reason our customers never have to wait for plans and specifications to be sent through the home office, as these are always handled locally, except in rare instances.

One of the items of service of which we are most proud, and concerning which we are frequently complimented, is our ability to estimate accurately and get our bids in quickly. We make a particular point of this with contractors and believe that the service is very much appreciated.

Road Show Space Allotted to 205 Exhibitors

Exhibit space at the Good Roads Show, to be held in the Coliseum, Chicago, Jan. 14-18, was allotted to 205 applicants in the manufacturing and allied fields at a joint meeting in Chicago, Nov. 1 and 2, of the executive committees of the American Road Builders' Association and the Highway Industries Exhibitors' Association and Charles M. Upham, convention and road show manager. The two executive committees were assisted by an advisory committee of six, each representing one of the six main classes of exhibitors.

Requests were filed for more than three and one-half times the main floor space available in the Coliseum. Applications for space in the Annex, the Ball Room, and the Greer Building also were in excess of the available floor area. While of necessity the space allotted to most applicants was less than they desired, the committee points out that due to a re-arrangement of aisles and exhibit areas every exhibitor will have adequate facilities for the display of his products.

Portland Cement Production

Production of portland cement established a new high record for the month of October when the output of United States mills, according to statistics of producers compiled by Ernest F. Burchard, of the U. S. Geological Survey, totaled 13,350,000 bbl. as compared with 13,109,000 bbl. in September, and 12,287,000 bbl. for October, 1922. Shipments for October of this year also showed a gain over those of the previous month, the respective figures being 14,285,000 bbl. compared with 13,698,000 bbl. Stocks, although diminishing, did not reach the low level of October, 1922.

Production of portland cement for ten months in 1923, amounting to 114,366,000 bbl., has nearly reached the total of 114,789,984 bbl. for the year 1922.

To Approve Use of Name-Plates for Standard Equipment

Until the Associated General Contractors' standardization organization is prepared to appoint a committee to test the individual types of concrete mixer equipment made by the various manufacturers with respect to adherence to the adopted requirements, affidavits by manufacturers will be accepted as indicating that equipment is complying with the terms of the coded standards. Upon receipt of each of these affidavits at headquarters, the privilege of using the standard name-plate will be granted.

The plates (see *Engineering News-Record*, Oct. 25, p. 699), will be furnished by the Joint Committee on Construction Equipment, of which Gen. R. C. Marshall, Jr., has been made trustee. The plates will be sold at nominal prices, probably ranging from 35c. to \$3.50, the sum being dependent upon the selling price of the equipment on which the plates are to appear. Any profit resulting from this sale of plates will be used by the Joint Committee to further the work of standardization of equipment.

Counterbalanced Window Sash for Industrial Building

Installation and Design Details Given for 90,000 Sq.Ft. of Glass in Studebaker Structure

APPROXIMATELY 90,000 sq.ft. of glass and 50,000 pounds of putty were required to glaze 1,681 units of counter-balanced sash and 592 units of sidewall (used in monitors) in the new six-story Studebaker building at South Bend, Ind., erected by G. H. Christman & Co. The installation of this sash, as well as 30 worm and gear operated

STUDEBAKER BUILDING'S LARGE WINDOW AREA

power units, and 1,552 lin.ft. of pipe was accomplished in 5 months.

Counterbalance sash is more difficult to erect than common factor or sidewall sash because the operation of all moving parts of the former must be accurately adjusted. As a result, the frame members are shipped in knocked-down condition to eliminate chances of their becoming jammed by rough handling in transit. When on the job the frame members are fabricated around the sliding sections, which are shipped assembled and ready for erection. Most of the windows in the Studebaker building were installed in prepared openings after the walls were up, and consisted of large bays, each containing five units of Fenestra sash supplied by the Detroit Steel Products Co., the source of the following notes:

Typical installation details for counterbalance sash are shown in the accompanying drawings. The concrete frame at the head and jambs are built offset with a rebate to accommodate the frame

WINDOW SASH DETAILS

Japan Awards Lumber Contracts

The Japanese Embassy on Nov. 14 advised the National Lumber Manufacturers' Association that the Japanese Government has awarded contracts for 97,150,000 ft. of lumber for use in building dwellings for Japan's homeless in the area devastated by the earthquake.

The Japanese Embassy said negotiations had been closed with these lumber companies: Douglas Fir Exploitation & Export Co., representing 108 West Coast mills, for 96,400,000 ft. of Douglas fir and Pacific hemlock; and Bratlie Bros. Mill Co., of Ridgefield, Wash., for 750,000 ft. of red cedar. The Embassy said that no information could be given by the Japanese Government at this time concerning the amounts involved in the contracts.

To Ratify Lumber Standards

"The lumber industry has taken a forward step in its plan for standardization of the industry."

Secretary of Commerce Hoover made this statement Nov. 15, commenting upon a plan submitted to him by the Central Committee on Lumber Standards. Mr. Hoover said he expected ratification of the Standardization plan Dec. 12, at a conference he has called, to be held at Washington, and to be attended by all elements of the lumber industry.

members. It will be noticed that the rebates of the jambs are much larger to allow plenty of room to grout the frames securely in position.

Detail 3 shows the type of mullion generally used when more than one unit is to be inserted in an opening. Bronze weathering sections of flaring channel are inserted at the jambs of the sliding units. These are riveted to the I-beam section in such a manner that they are entirely covered by the equal leg jamb section of the sliding unit. The object of this design is to insure excellent weathering qualities.

Detail 1 shows a typical stone sill and brick curtain wall. Grout is poured into the frame through holes provided for that purpose.

For simple operation with this type of sash the upper and lower sections are hung at the ends of chains which run up over pulleys at the head of the jambs. When the lower unit is pulled up, the upper goes down. The overlapping members of the sash unite, provide effective weathering and prevent wind and rain from driving through.

When installing the sash head and jamb frame members are bolted together and set up in the opening. If mullions are to be used they are attached also at the head. Then the sliding sections are slid up in frame from beneath. The sill member is fastened to the jamb by means of adjustable sill clips, slotted, to allow proper adjustment of the sections and insure sufficient clearance for easy operations.

Glazing is done after the sash has been grouted in. The units are locked tightly shut; bed putty is applied and the panes of glass inserted. Glazing clips for holding the glass securely in place are inserted in the holes provided for them in the muntins. Then the final layer of putty is applied and the job is done.

Municipal Equipment Shown at Atlanta Convention

Paving Materials Chief Feature at A.S.M.I. Meeting—Trucks, Sweepers, Pipe and Valves

EQUIPMENT and materials employed in municipal service were the feature of the exhibit held in connection with the annual convention at Atlanta, last week, of the American Society for Municipal Improvements. Paving materials predominated among the products on display; of 29 manufacturers represented 12 were in the paving field. The following list gives the companies which had exhibits and the nature of their products:

The White Co., Cleveland. Motor trucks in municipal service.
Phoenix Portland Cement Co., Birmingham. Cast urns, samples of raw materials.

Granite Paving Block Association, Boston. Granite blocks.

National Paving Brick Manufacturers' Association, Cleveland. Paving brick.

Portland Cement Association, Atlanta. Pipe, concrete blocks.

Smith-Winn Co., Atlanta. Insurance agents.

Philip Carey Co., Cincinnati. Elastic expansion joints for concrete paving.

Georgia Railway & Power Co. Atlantic Refining Co., Philadelphia. Asphalt.

Yancey Brothers, Atlanta. Caterpillar tractors and contractors' equipment.

Birmingham Slag Co., Birmingham. Concrete aggregate.

W. S. Goodwin Co., Baltimore. Steel paving guards.

American City, New York. Asphalt Association, New York. Asphalt pavement.

Shearman Concrete Pipe Co., Atlanta. Pipe.
Link Belt Co., Philadelphia. Brush and Brush Mount for Tark sewage screen. Also conveyors.

U. S. Asphalt Refining Co., New York. Aztec asphalt, filler for brick pavement.

Pittsburgh Testing Laboratory, Pittsburgh.

Ludlow Valve Mfg. Co., Atlanta and Troy, N. Y. Valves and hydrants.

Manufacturers Record, Baltimore.

Sam E. Finley, Atlanta, Ga. Pavements.

Kentucky Rock Asphalt Co., Louisville. Rock asphalt pavement.

Lock Joint Pipe Co., Ampere, N. J. Concrete pipe.

Catch Basin Products Corp., Indianapolis. Sewerage accessories.

Warren Brothers Co., Boston. Bituminous pavement.

Public Works, New York.

Willite Southeast Co., Atlanta. Bituminous pavement.

Elgin Sales Corp., Chicago and New York. Street sweepers, motor driven.

F. W. Sampson, Atlanta, Ga. Vibriolithic pavement.

Pumps Exported

According to figures issued by the Department of Commerce domestic exports of pumps for the month of September totaled 145 units valued at \$63,816. Cuba was the largest purchaser with 28 pumps at \$15,691.

Business Notes

CLEVELAND CRANE & ENGINEERING Co., Canton, Ohio, announces the opening of a new office in St. Louis, Mo.

IRVING IRON WORKS Co., Long Island City, N. Y., manufacturer of subway grating and safety treads for stairways, held a three-day sales convention in New York recently, at which about 40 representatives of the company were present from various cities of the United States and Canada. The speakers at a banquet on the evening of Sept. 12 included W. E. Irving, president; P. L. Price, general manager; M. K. Griggs, representative at Houston, Texas; A. T. Vonier, representative at Milwaukee, and W. McKee, of the production department.

W. & L. E. GURLEY, Troy, N. Y., announce the establishment of an office at 364 Monadnock Block, Chicago, in order to serve mid-west customers more efficiently and expeditiously with their engineering and surveying instruments, plane tables, current meters, water-stage recorders and other appliances. C. H. Smart is in charge.

Equipment and Materials

Rotary Pump Delivers Continuous Flow From Deep Wells

For pumping ground water in connection with irrigation and drainage operations the Worthington Pump & Machinery Corp., New York, has developed the Axiflo deep well pump which, by means of an impeller of the general form of a ship propeller, and discharge vanes delivers a continuous flow claimed to be considerably greater than that obtainable from any other type of deep well pump except the air-lift. The unit is designed for operation within an 18-in. well casing and is driven through vertical shafting by an electric motor or a belt drive from steam or gasoline engine at the ground surface. For shallow wells a single impeller is used, but in deep wells their number

is increased, thereby making the pump equivalent to a multi-stage unit.

The impellers are made of bronze. The discharge vanes are designed to eliminate eddying currents and their accompanying waste. The shaft is of nickel steel and is divided into easily handled lengths, coupled together by long steel couplings. The weight of the moving parts and the water column thrust is taken up in specially designed three-plate, self-adjusting bearings,

which run submerged in a water-jacketed oil bath.

Three of these deep well pumps were supplied to the Salt River Valley Water Users Association in Arizona for delivery of 4,000 gal. per minute each from 18-in. wells involving lifts of 30 and 40 ft. Tests after installation showed efficiencies as high as 72 per cent, delivering the specified flow.

A New One-Man Track Jack

A single-acting track jack for operation by one man in surface and under normal track loads has been brought out recently by Templeton, Kenly & Co., Chicago, and is known as the No. 217 Simplex jack. A load of only 27 lb. at the end of a 66-in. lining bar inserted in the socket is sufficient to lift 1 ton, so that a 150-lb. man can lift 4½ tons, which is well within the loads

encountered in ordinary work where main track is raised 1½ to 2 in. for surfacing. The total capacity of the jack is 15 tons, so that it is strong enough for such heavy work as raising crossings.

Increased power in the new design is obtained by the use of trunnion, instead of pin, construction for the socket, thus shortening the distance between the bearing and the pawl seat. It was necessary also to reduce slightly the pitch of the lifting rack, but it is stated that while the lift for each stroke is less the jack is more rapid in operation as it works so easily that the operator makes quicker strokes. The total lift is 13 in. All parts except the socket and standard are heat-treated forgings of carbon steel.

Publications from the Construction Industry

Power Drag Scrapers—SAUERMAN BROS., Chicago, has issued a 31-p. illustrated pamphlet on its power drag scrapers, with buckets ranging in capacity from ½ to 2 cu.yd. The text describes several forms of patented bucket including the Crescent and the LeClair, and then takes up power requirements and handling capacities. Succeeding pages describe both in text and picture the application of the equipment to different kinds of work.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Water-Works Installation This Year and Last

Water-works construction in the United States has followed a remarkably regular curve this year, according to *Engineering News-Record* statistics covering contracts of \$15,000 and over. The first two months were normal, though about \$2,000,000 per month above 1922. March was abnormally heavy, owing to \$10,330,462 worth of Catskill Aqueduct contracts being awarded for a syphon to Brooklyn and conduits in that borough. Since March the slope has been fairly uniform, in August falling below 1922 figures. Contracts in the last two months have continued lighter than those let last year.

During the first nine months of the two years under consideration, 1922 had 327 awards with a total value of \$25,000,000 against 335 for 1923 valued at \$51,000,000. The average value of each contract in 1922 was \$77,889 compared with \$153,074 of this year. The trend of water-works installation for the United States during the last four years (for nine months in each case) may be gathered from the following figures:

Year	Value	Monthly Average
1920	\$16,401,000	\$1,822,000
1921	24,252,000	2,695,000
1922	25,470,000	2,830,000
1923	51,280,000	5,698,000

The significant fact is the same as that pointed out in the case of industrial work (p. 784, this section, Nov. 8 issue), that although the year started off with a rush of work, there has been a steady decline in the last half of the year. The Middle Atlantic states and the Mid West have been by far the most active in water-works construction this year, though both these sections are running low at present.

The October, 1923, record was hung up by the Far West, and included a 25-mi. conduit for Portland, Ore., price \$2,571,404. A glimpse of the situation in the various sections of the country is given by the following comparison of the number and value of projects in the first nine months of 1922 and 1923:

	1922		1923	
	No.	Value	No.	Value
New England	12	\$2,754,000	8	\$671,000
Middle Atlantic	56	5,972,000	55	20,704,000
Southern	40	2,602,000	25	2,676,000
Middle West	85	4,828,000	111	13,518,000
West of Miss.	103	4,899,000	116	10,120,000
Far West	31	4,414,000	20	3,389,000
Total	327	\$25,469,000	335	\$51,290,000

Importation of Foreign Cement Affects Sewer Bids

The importation of foreign cement at Los Angeles Harbor has been steadily increasing during the past year, and is having its effect on the local construction situation. The presence of foreign material at the harbor last summer seems to have resulted in lower bids for the large quantities of material required in the construction of the Los Angeles outfall sewer. At least this was the opinion of engineers connected with that particular job.

During July, August and September of this year, the total receipts of the foreign material amounted to 47,420 tons, while for the corresponding period of 1922, no receipts were recorded.

Segregation by countries from which cement was received during this third quarter of 1923 is indicated by the following table:

England	16,783 tons
Sweden	16,774 tons
Belgium	6,041 tons
Germany	3,761 tons
Norway	3,083 tons
Denmark	1,435 tons

Total 47,420 tons

The value of this cement according to figures of the City Harbor Commission was \$503,769. During the busiest part of the 1923 building season in this vicinity, there occurred a shortage of native cement and this was the reason for the bringing in of appreciable quantities of the foreign material.

Whether or not the importing of the foreign cement will be continued, depends upon the ability of dealers in the local materials being able to meet the demands. It is understood that native cement is now being stored by local producers in anticipation of the heavy demands which are expected in the Spring of 1923.

Cement contracts for the outfall sewer were awarded to three American companies for 40,000 bbl. each, at \$2.55 per bbl., without bags, f.o.b. cars at mill. Although foreign competition brought the bids to a comparatively low figure, the prevailing price in Los Angeles is \$3.16 per bbl. in carload lots, without bags. Several Western cities, however, are reporting declines.

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for in Construction News, pp. 279 to 290, are the following:

Hotel, Tacoma, Wash., Citizens Hotel Corp., Inc., \$1,500,000.
School, Baltimore, Md., Johns Hopkins Hospital, \$1,000,000.

High School, Brooklyn, N. Y., Supt. Bd. Educ., \$3,000,000.
Hotel, Memphis, Tenn., W. W. Ahlschlager, archt., \$3,000,000.
Seminary, Webster Groves, Mo., T. P. Barnett, archt., \$1,000,000.
High School, Hartford, Conn., Bd. Contract & Supply, \$1,200,000.
Canal, St. Catharines, Ont., Dept. Rys. & Canals, \$5,000,000.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted. Valuable suggestions on costs of work can be had by noting actual biddings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Nov. 1; the next, on Dec. 6.

Explanation of Prices:—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or — signs. For steel pipe, the prevailing discount from list price is given: 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b.

Labor—Concrete laborers' rate, 93 $\frac{1}{2}$ c.; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. Tile price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu.yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5 $\frac{1}{2}$ x 8 x 11 $\frac{1}{2}$. Prices are all f.o.b. warehouses except C. I. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir, common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on white pine lumber, free on cars at mill. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 98.80). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$47.43; 6-in., \$119.

Changes Since Last Week

For every factor favoring the expansion of business in the current market, there appears one equally unfavorable in nature. For instance, the volume of business, generally, is large, particularly in the retail trade, with little falling off in consumption; export trade is gaining; an optimistic impression has been created by the suggested Federal tax reduction and price declines have occurred in pig iron, cement, clay products, linseed oil, lumber, leather, etc. In contrast with these, come reports of uncertainty in the stock market; lower foreign exchange rates and unemployment in certain manufacturing trades consequent to curtailment of output. It is also

noted that buyers, having stocked up earlier in the season are now confining purchases to a "hand to mouth" basis.

The only price advances received from eight cities, reporting weekly to *Engineering News-Record*, was a rise in Montreal of 25 cents on steel shapes and 10 cents per 100 lb. on reinforcing bars. Seattle also reports an upward trend in lumber due to demand from Japan and California.

Declines, however, were reported in cast-iron pipe and common brick in New York; cement in Minneapolis; pine lumber in Montreal; linseed oil in Dallas, Minneapolis and Denver. The linseed oil drop reflects the influence of flaxseed receipts as well as

of current demand for paint stuffs.

Bookings of commercial steel castings and steel structurals fell off perceptibly during October. Shipments of locomotives from principal manufacturing plants during the first ten months of 1923, increased 183 per cent over the corresponding period in 1922. Orders have been received by the American Locomotive Co. for eighteen locomotives for the Southern Pacific and twenty-five for the Delaware, Lackawanna & Western R.R. The Baltimore & Ohio R.R. awarded contracts to the Pressed Steel Car Co. for 500 all-steel hopper cars of 55 tons capacity, and to the American Car & Foundry Co. for fifty steel box cars.

South Against West

WHERE shall national funds be spent for making unproductive land fit for agriculture? In the West, or in the South, or in both? That was the major theme of the reclamation conference held at New Orleans last week. The West had its innings during the past twenty years, and now the South is ready for its turn, and it calls upon the West to help it get it. There were addresses and thoughtful discussions of the common interests of West and South, it is true, and as our report of the conference (on another page) indicates there was a general spirit of working together. Yet at bottom the situation brought before the public by this movement is one of competing demands—of the West for further federal expenditure in irrigation, of the South for the financing of drainage and land-clearing work along its coasts. The question of paramount public concern of sound national policy in reclamation investment received only minor notice. It seems to be taken for granted that government funds should and must needs be given for land development work. Yet it is this point which the citizen at large demands to have settled first of all. Once a basic policy is established, and a system of administering it with full success is devised, the apportionment of expenditures between geographical sections will be easily accomplished, and no logrolling will be needed for satisfactory adjustment. The permanent Southern Conference can do nothing better than deal with the present reclamation problem and help in solving it; this once solved, and the need for federal reclamation work as well as a sound method for the work determined, the claims of the South will be satisfied without further demand.

Sources of Road Funds

A STIMULATIVE study in highway finance, as reported by the committee on finance of the Advisory Board on Highway Research of the American Research Council, is published in this issue. The road funds of four counties in Wisconsin are traced from source to destination. Incidentally the same sort of investigation is now being made in other states, with indications at present that the evidence will confirm the Wisconsin findings. In brief, these are that the bulk of all expenditures for all roads are county and township funds and that the bulk of all funds for all roads is provided by taxes on property and income. The precise figures are given in the committee report. Leaving the economist and the taxation expert to draw their own lessons from these figures, what conclusions do they suggest in respect to the extent of competent engineering direction of all expenditures for road improvement? We can reason only from inference as the committee report does not touch this subject. The inference is that the bulk of county and local road funds are spent under the sole supervision of county and township high-

way officials. State and federal expert engineering direction dictates only the lesser part of all highway expenditures. It influences county road expenditure in a varying measure and is altogether remote from township expenditure.

Misinformation on Muscle Shoals

ONE of the great disadvantages of having a silent President—we will not attempt to sum up the advantages—is that it affords such wonderful opportunity for the Washington newspaper men to put thoughts into the executive head. A sample is the recent flood of reports from the capital as to the President's attitude toward Muscle Shoals. These reports, whether they represent Mr. Coolidge's mind or not, are most discouraging for they indicate that Washington newspaperdom, in spite of its exceptional intelligence, does not understand the Muscle Shoals situation or the Ford offer. The gist of the reports is that the President is now contemplating the construction of a steam plant at Florence so that Muscle Shoals may be made sufficiently attractive to make Henry Ford forget his ill temper at the sale of Gorgas to the Alabama Power Co. and renew his offer for Muscle Shoals. This is pure Ford propaganda. Those who have followed the case know that the one or two million dollars involved in a steam plant is a drop in the bucket compared to the perpetual franchise Ford is asking the government to give him in violation of the water power law of the country. To present the government in the rôle of a suppliant to Henry Ford is ridiculous.

Municipal Treason

NEW YORK CITY'S commercial interests are in one of their periodical fits about the diversion of business to other ports. They have found out again, it seems, that while New York still gets almost all the transatlantic business certain other ports are growing faster and they scent a railway plot to build up a southern rival. Thereupon they urge the rearrangement of the port's facilities, not necessarily to reduce the cost of handling freight but to insure an increase in the amount of freight handled. And every New York business man, listening to the dire prospects of a luncheon speaker's prophecies, feels that somehow his personal fortune is dependent on that increase in amount of freight handled. This delusion of size is not confined to our largest city, but it is more ridiculous there than elsewhere. New York is big enough, but by its own metropolitan attraction it will continue to grow. In that growth it will not become a better place to live in or to do business in, nor will many individuals profit more than they already do. What will happen is that more individuals will flock there to take their profits, and by so flocking increase the unit cost of living and of doing business, an increase that is a charge against the whole nation which pays a tax on all the goods that moves through the metropolis. If some of

this new business can be diverted elsewhere, New York and New Yorkers will not suffer—except in self-esteem—and the rest of the country will benefit. No one can set the optimum limit of size in our cities but few will doubt that a number of our biggest cities have passed it. If this be treason let the Chambers of Commerce of our cities make the most of it.

Highway Transport Surveys

THERE is a distinction between a transport survey and a traffic census which needs to be more often remembered in taking account of highway traffic. There are few states which have made transport surveys of any sort and only one state which has carried to anywhere near conclusion a state-wide transport survey. More states, in all about forty, have made some sort of traffic count, most generally of a local character, which may be designated as a traffic census. These statements are drawn from a tabulation of "traffic surveys" by states prepared by G. E. Hamlin, whose report on highway traffic analyses to the Advisory Board on Highway Research of the National Research Council, is published in abstract in this issue. The significant value of this tabulation is the clear indication that beyond general observation highway engineers have no knowledge, except in one or two states, of state-wide traffic conditions. They are proceeding, with road planning virtually without precise knowledge of road use. They are entirely safe in doing this because no matter where or how fast roads are built the traffic is there, or almost immediately develops, to put them into full service. Conditions are arising, however, which put another aspect on the situation. The safe task of deciding that traffic warrants turning an unimproved trail into an improved road or a surfaced road into a paved road is giving way to the hazardous task of telling when three-way or four-way roads, with heavy pavement sections, are economically justified. The traffic counts of the past, either in scope or precision, are not sufficient for the present and are totally inadequate for the near future, and already in many states and localities, need to give way to the transport survey.

Unwise Taxing

THE United States is alone of the great commercial nations in levying an income tax on its nationals who are earning an income in trade or profession in foreign countries where they reside and where the local nation taxes all residents of whatever citizenship. For some years there has been agitation to abrogate this feature of the income tax law but it has been so far successfully opposed probably because there has been fear that any such revision would also relieve from taxation the expatriate who is living on a nonearned income. The law is so serious a drain on our foreign trade, however, that every effort should be made in the coming Congress to write an amendment which would not protect the expatriate capitalist but which would make foreign trading or professional practice less of a burden than it now is. Secretary Hoover in a recent address put the case clearly. In the field of engineering alone the situation is deplorable. "Before the war," said the Secretary, "there were at least 1,000 American engineers employed at substantial salaries in the territories of our former allies. These men went abroad to install American methods, American machinery and

equipment in the production of raw materials, and in transportation. These salaried workers now find themselves subject to two gigantic income taxes and thus their foreign mission is unprofitable. I doubt whether there are 100 of them left in foreign territories today. A vast amount of American machinery and equipment that followed in their wake has dried up." So long as the other great producing nations absolve their foreign residing citizens from the rigors of a tax on earned income, there will be increasing difficulty in getting Americans to compete in a field where they have to pay a double tax.

A Demonstrated Danger

A DISTINCTLY new situation is created by the fact that on two separate occasions within the past couple of years secondary bending in the members of a framed structure has led to failure. In both instances the affected structure was a bascule bridge, a structure which experiences greater stress variations than a fixed bridge. It happens also that the two bridges were of the same type. This fact, however, is of less interest than the demonstration which the two accidents give that there are dangerous potentialities in an action which heretofore engaged little more than academic interest on the part of structural engineers.

Bending effects due to truss distortion, or secondary stresses, are accorded a courtesy recognition in textbooks and in design specifications dealing with bridges, but do not often receive more serious consideration. In structures other than bridges they are practically ignored. Many engineers lean toward the view that though they may theoretically exist they have no practical meaning, certainly none comparable to load or wind stresses—in effect that secondary stresses do not involve any risk of failure of a structural member. It is therefore of decided importance to learn from actual failures that these stresses represent a tax on the material in just the same way as direct load stresses, and must receive a similar accounting in the proportioning of members.

The first case, which occurred two years ago, involved the large double-leaf bascule bridge of the Canadian Pacific Ry. at Sault Ste. Marie, Mich. Each leaf is counterbalanced by a concrete counterweight hung from the rear end of a pivoted truss or walking beam that is trunnioned on a tower over the abutment. The bottom-chord member of one of these walking beams broke square across while the bridge was being operated, and the break opened up half an inch or so. The member in question is short, wide and very rigid, and, as the truss triangle of which it forms one side necessarily undergoes repetitive distortion under the varying stresses set up during the operation of the bridge, this rigid member was subjected to severe secondary bending whenever the bridge was raised or lowered. Such bending actions, continued for several years, evidently broke the stiff chord by detail fracture. Not as much is known about the detailed circumstances as would be desirable, as the railway company unfortunately has not made public any information concerning the accident, the analysis of causes or the repair operations; but there can be little doubt that the responsible action was as outlined. This view is confirmed by the fact that some time prior to the fracture an adjoining member of similar proportions and stress relations was found to require repair because of incipient frac-

ture. Moreover, both this weakness and the subsequent fracture were close to a heavy panel-point, where secondary stresses are at their maximum.

Last month a small bascule of similar type near Montreal was the subject of an equally interesting failure, again involving the counterweight support but this time localized in the members which projected down into the counterweight and carried its load as hangers. On this case a statement of conditions was made by the designers, as printed on page 861 last week. Excessive bending stresses, the statement indicates, resulted from the removal of side plating of the counterweight and from defects of the early design. Whatever their source, their effect in producing ultimate rupture of one hanger (which in turn led to failure of the others) presents a valuable confirmation of what the Soo accident indicated, namely that secondary bending is quite capable of producing failure.

Whether the potential danger from this kind of stress is as great in fixed as in movable bridges may be open to question, as the variable part of the truss distortion is generally smaller in fixed structures. This point will probably engage the attention of practical bridge designers, a remark which also applies to quantitative appraisal of the influence of secondary stress. Even without such detailed consideration, however, we gain from the two accidents the important knowledge that secondary stresses are by no means negligible but that on the contrary they threaten the safety of structures just as truly as do the more commonly calculated stresses. In the light of this new fact it would seem that safe designing will need to take account of them by calculation, as for the direct load stresses. The procedure now prevalent of assuming that secondaries do not exceed certain percentages of the load stresses is hardly adequate to meet this requirement, especially since it is considered necessary nowadays to compute less vital actions to an accuracy of two or three places.

Associated Professions

SOME weeks ago we noted the strange situation in the State of New York whereby students of engineering are barred from aid of state scholarships and expressed some curiosity as to the theory which underlay such a peculiar law. Since then we have received a memorandum from the State Department of Education, which contains the following paragraph:

"The scholarship law provides that no scholarship shall include professional instruction in law, medicine, dentistry, veterinary medicine or theology, except so far as such instruction is within a regularly prescribed course of study leading to a degree other than in the above-named professions. Since the enactment of that law, pharmacy, chiropody, optometry, architecture, and engineering have been added to the professions and to practise in such additional professions a license from the state is required, as was true of those professions named in the original law. It was argued that if a person was to receive the manifest benefit accruing from a state license to an individual obtaining the same, the state ought not in addition thereto to contribute to the education of such individual and that the original purpose of the law was not to aid men primarily in securing an education in a school that was to prepare him for the practice of a profession but rather to encourage the higher education in those courses which are more largely literary and cultural."

The mystery as to the real reasoning behind the law

becomes more involved than ever. Two things, however, are clear: First, that the state's educational directors conceive of the license to engineers as a beneficent bestowal of grace upon that profession and not as a protection to the public and second, that engineers in the State of New York now have been elevated to the same professional status as the chiropodist. We might also remark the state department's conjunction of the term "literary and cultural," though we had thought that in educational circles that synonymy was no longer accepted. The most pertinent conclusion that can be drawn from this strange combination of ambiguity and unfairness is that the New York State Department of Education needs a little educating itself in modernism.

Tardy Highway Research Records

A SIGNIFICANT comment on highway research is contained in the report of Prof. W. K. Hatt, Director, Advisory Board on Highway Research of the National Research Council:

In the three years much progress has been made in quickening the will to research, in mobilizing the energies of research agencies and in assembling the data necessary for judgment upon questions of highway planning, construction and operation.

It may be said with a large degree of confidence that at present a well trained and experienced highway engineer, in possession of available data, can select a type of highway suitable to the conditions of climate and traffic of a given situation, can specify the materials and design the section with a reasonable certainty that it will withstand the specified conditions of service.

It is true that the communication of these data to engineers in general has not kept pace with the accumulation of the data nor has a working organization for the process of analyzing the data and translating the discovered principles for the use of engineers been adequately provided. The Advisory Board has published bulletins of information on existing research projects, on apparatus for research and the director has written many occasional papers. Its research committees have summarized progress. Much remains to be done, however, in unlocking the stored-up data in the files of the state highway commissions which are now such active agencies in highway research.

One who has some acquaintance with the research work being done will readily subscribe to Prof. Hatt's statement. It is the last paragraph however which commands particular attention. Research data in highway engineering and transport are being accumulated much faster than they can be communicated to highway engineers chiefly because means are lacking to undertake publication and because complete publication being thus denied there is a disposition by investigators to withhold summaries and conclusions brief enough to be given expression in engineering journals.

In most highway research investigations there is an unconscionable delay first in analyzing the amassed data and second by hoarding the results until the last drop of uncertainty has been wrung from them. It is these facts which hold back to a considerable degree financial support from commercial interests. Contributions for highway research would be far more plentiful were the donors assured of a reasonably prompt communication of results. Communication would be reasonably prompt if research workers utilized the means of communication available and trusted to future opportunity for publication of the compendious and definite report naturally craved by the investigator proud of his work.

Current Structural Research at Bureau of Standards

Many Studies of Metals and Structures Recently Completed or in Progress—Extensive Work Being Done in the Field of Cement, Brick, Hollow Tile and Stone, Including an Investigation of Stucco Foundations

MUCH WORK is going on at the Bureau of Standards that has direct bearing on the materials and design methods of civil engineering construction. Besides dealing with the properties of materials themselves, this work concerns the action of structures—from beams and columns to completed buildings and cranes—and their details. New materials or new difficulties figure in some of the work, as the duralumin members of dirigible airships, the low mechanical strength of zinc corrugated roofing, and disintegration troubles in Western sewers. Well-known constructions also present new questions constantly, as exemplified in tests of riveted joints recently begun for the Navy, and a reinvestigation of stucco with respect to the effect of foundations that is shortly to begin. Brief notes on various items of this work recently gathered at the Bureau are given in the present article.

Tests of Structures—Two interesting stress investigations of completed structures were carried out some time ago by members of the Bureau's staff, but only recently reported on. One of these was a measurement of stresses under measured floor loads in a reinforced-concrete building in Washington, the Arlington Building, undertaken primarily to give assurance of the safety of the structure after its floors had been strengthened by applying an additional thickness of concrete on top of the previously completed floors, to increase the load capacity of the floors. The tests showed that the expedient was reasonably effective.

Tests of stresses in the framework of the 350-ton tower crane at the Philadelphia Navy Yard, which were strain-gage measurements made under known loads, showed close agreement with calculated results. The tests were not fully informative because they related only to live-load stresses; dead-load stresses could not be measured because gage points had not been provided on the members before erection.

Column Tests—Much investigative work in the field of columns has been going on. In connection with test work, a theoretical study of column action along the line of Karman's attack on the problem is under way, and a restudy of the column tests carried out for the American Society of Civil Engineers seven years ago has been carried out, the latter by an outside investigator, Prof. O. H. Basquin.

The most elaborate of the column tests was a series of ultimate strength tests of about 150 members of the framework of the navy dirigible airship ZR-1, just completed at Lakehurst, N. J. Most of the members tested were of triangular cross-section, 8 to 13 in. in depth, and in 3, 5, and 10-m. lengths. About one-half of the total number were tested as columns, the others as beams or under combined column and beam loading. The column tests were made with round ends, using ball-bearing spherical blocks. In the beam tests, under distributed loading, a failing stress of about 22,500 lb. per square inch in the extreme fiber was developed, the results being quite consistent. The column tests were also satisfactorily consistent; ultimate loads ranging from 3,300 lb. per square inch for the longest

columns to 22,000 for the shortest and thickest columns were obtained. The failures were substantially all flexural, that is, dependent upon the elastic properties of the material and dimensions of the structure, rather than due to passing the yield-point of the material in short-column action, and there were no rivet failures or failures caused by poor material or poor workmanship. In a few cases the buckling was integral, with bending of the column, but in most instances the section of main channel between lattice bars buckled. The longer columns, from slenderness ratio 170 down to 80, fitted the Euler curve with modulus of elasticity taken at either 9,000,000 or 10,000,000 lb. per square inch. Shorter columns showed strengths flattening away from the Euler curve to a horizontal at about 18,000 lb. per square inch. The material itself is reported to have a yield point from 30,000 to 35,000 lb. per square inch.

The fact that channel buckling was found to be the determining factor in the strength of these girders has led to an investigation of the effect of channel thickness and shape upon the buckling stress. This investigation which has just been started is expected to continue during the year.

Compression tests on 170 structural steel angles, ranging in slenderness ratio from 350 down to 50, were recently reported. In the longer angles the effect of the end connections was marked, but became less noticeable in the shorter angles where the yield point of the material became the controlling factor.

Fourteen wide-web columns were tested for the Delaware River Bridge Commission. The webs were 35 in. wide by 10 ft. long and ranged from $\frac{3}{4}$ to $1\frac{1}{2}$ in. in thickness, the thicker ones being made up of two plates. The flange angles were 6 x 4 x $\frac{3}{4}$ in., but were supported by stiff members transverse to the web plane, to prevent flange buckling. The strength of these assembled columns ranged up to 44,000 lb. per square inch, nearly all the specimens coming close to this value except one, in which the test conditions were somewhat irregular. Thorough exploration of the buckling action of the web plates was carried out, and this study appears to show that for the columns tested there is a critical value at about $\frac{3}{4}$ -in. web thickness, the failure of the thinner webs being due to web plate buckling. When buckling does not occur the web remains undeformed until the proportional limit of material is reached.

Two extended series of tests of heavy structural columns were carried out for the American Bridge Co. and the Bethlehem Steel Co., including respectively about forty and thirty columns. In both series, built-up and solid-rolled column sections were included, and the length ranged up to 24 ft. and the metal thicknesses up to $2\frac{1}{2}$ in. in the flange, with total cross-sections up to 85 sq.in. In general, both series showed that difference in the strength of these columns were almost wholly due to differences in the tensile yield-point of the material. There was a wide variation in the yield-point of the material in the different specimens, but in all cases column strength was directly related to the yield-point of the material obtained in small specimen tests. Yield-

points as given by mill reports, however, could not be used in the comparison, being quite wild.

In the theoretical study of column strength in progress at the Bureau, small sized compression specimens of various lengths are to be tested, with knife-edge end-bearing carefully centered. The relation of column strength to compressive test specimen qualities will be one of the matters investigated. In the tests of large columns, above noted, only tensile specimen yield-points were available.

Tubes as Columns—A series of steel tubes of thin gage, in diameters ranging between 1½ and 2½ in., was

COLUMN TESTING IN TEN MILLION-POUND MACHINE

This specimen is a steel column of solid rolled H-section, and withstood 3,063,600-lb. total load before failing. The dimensions and weight of this specimen are as follows: Length, 22½ ft.; sectional area, 55.1 sq.in.; total weight, 6,800 lb.; slenderness ratio, 73.0. The four vertical rods near the screws are attached to the upper head and operate dial micrometers attached to the lower head. They measure the relative movement of the testing machine heads and show any tilting as the test proceeds. Four other dial micrometers show any lateral displacement of the lower head. Four compressometers were attached to the column extending over about half its length, to measure the shortening of the column.

tested for longitudinal compressive strength. The specimens varied greatly in the tensile yield-point of the material, which was reflected in the compressive strength. Eccentricity of loading due to difference of thickness on opposite sides of the tube also was a factor, tending to produce early bending. In general, failure occurred by local buckling or cinking rather than by integral bending.

Welding and Riveting Compared—Comparison of welding and riveting was carried on in several series of tests. Spot welded joints of plates were tested in comparison with similar riveted joints, and corresponding tests were made on plate girders and on built columns. The welding was done by two methods, in one of which

the current was concentrated at the point to be welded by placing a small copper disk under the electrodes, while in the other the metal of the plate was embossed by a shallow die before applying the electrodes, for the same purpose. No perceptible difference between the two methods of welding was noted.

In plain tension tests of joints, the welded specimens showed up fully as well as the riveted, giving higher strength in a number of instances. In the tests of girders, no particular difference was observable, except that the welded girders showed about 5 per cent greater deflection than the riveted girders. The welded columns were weaker than the riveted, by about 13 per cent; this may be due to a greater flexibility corresponding to that found in the girders. In the opinion of the mechanical test department, these test series, while illuminating, were not sufficiently extensive to warrant definite conclusions as to commercial serviceability of the welding method. More extensive static tests and in connection with them some fatigue tests would be required. The fact that the welded joints in most cases showed greater elongation than the parallel riveted joints was, however, considered an important indication of the good quality of the joints.

Comparative tests were made of three welded and one riveted tank, for comparison with each other, extensometer measurements being made on the tanks. It was found that the commonly accepted theory for the design of tanks is, for all practical purposes, sufficiently accurate, provided the computed stresses are not influenced by secondary stresses. Secondary stresses which resulted in high stress intensity in these tanks were caused by (a) faulty design of the attachment of the spherical end to the cylindrical shell, (b) non-conformity of the shell to an accurate circular section, and (c) discontinuities in the shell for the manhole and fittings.

To aid in the preparation of the new A. S. M. E. Safety Code for unfired pressure vessels, over 40 welded tanks furnished by the American Welding Society were tested to destruction under hydrostatic and combined hydrostatic and hammer test. The superiority of the double Vee over the single Vee weld and useful information for the design of welded pressure tanks was shown by these tests.

Riveted Joints—An unusually elaborate set of tests on very large riveted joints has just been begun for the Navy Department. The tests have the main purpose of throwing light on the best proportion of riveted seam connections such as those used in ships' plating, when special steel is used for the plating. About 100 specimens are to be tested, each 22 in. wide, with as many as twenty rivets on a side. Three weights of plate and three grades of steel—structural, high carbon, and alloy—with rivets of medium and of high strength are included. The main objective is to determine the best distribution and the best type of joint, using up to four rows of rivets. The full program in prospect is much larger than that indicated by the above number of test specimens.

In these tests, the stress measurements will cover the middle 5 ft. of length, the test pieces being 8 ft. long overall. In addition to extensometer measurements, the cement wash method of outlining the stress line produced during deformation will also be applied. The specimens have widened ends, bolted to machine head

fittings, to make the stress distribution on the test length as uniform as possible.

Wall Tests—Walls of hollow tile were tested under endwise loading during the past year, with results just made public. The walls were 6, 8 and 12 in. thick, 4 ft. long and 12 ft. high, all laid up in cement (4) lime (1) mortar. The ultimate strength of these carefully built walls was in the neighborhood of one-third the strength of the tile tested singly, but quite wide differences in strength of the tile did not greatly influence the results, and the stress at failure (net sectional area) did not appear to depend to any noticeable extent on the thickness of the wall or the size of the tile. End construction walls were about twice as strong as side construction walls. Strain-gage readings on the walls proved to be of little use. Tests on a few walls with eccentric loading applied over half the thickness of the wall gave reduced strength. These tests were reported by H. L. Whittemore and B. D. Hathcock.

Tests of brick walls and piers are to be continued. In the former, the effect of cement, cement-lime and lime ("Ideal" construction) mortars on hollow and solid walls, made of different kinds of brick, will be studied, in walls either 8 or 12 in. thick, and about 6 ft. long and 12 ft. high. The tests of piers are likely to be planned on a large-scale basis to develop the effect of bond, kind of mortar, method of laying, and the like.

Various minor tests of special structures have been carried out that may be noted here. They include tests of wire rope sockets and tests of large capacity crane hooks of the type used in lifting girders. In the latter, it was found that design on the basis of the method used for straight beams is satisfactory. In some tests of the effect of looseness of fit between nut and screw on the tensile strength of a bolt, little effect of the tightness of fit was observed. In connection with the miscellaneous work of the Bureau in this field, mention may be made of a specification for wire rope, recently issued, representing a compilation of commercial practice to represent a high grade of commercial steel wire rope manufacture, rather than a formulation based on test results. The specification is an attempt to standardize twist, core, quality of galvanizing, and strength, for four grades of rope in both galvanized and uncoated material.

Strength of Corrugated Zinc Roofing—Among the tests in the field of special materials, strength tests of corrugated zinc roofing are included. These developed from doubts arising out of practical experience as to the proper spacing of supports for such roofing. The material when under continuous load shows slow, progressive sagging, and no conclusions have yet been drawn as to the proper working stress for design, but the present result indicates that the purlin spacing must be considerably less than with galvanized steel roofing of the same gages. In connection with these tests, fasteners such as zinc nails are also being tested.

Fatigue of Sheet Duralumin—Elaborate flexural fatigue tests of sheet duralumin are in progress, being part of a program on which work has been proceeding for several years. Thicknesses of 0.020 to 0.120 are under test, in samples about 1 in. square. Bending is applied in alternate directions, the stress being measured at each alternation by a spring gage at one end of the specimen. The applied stresses are below the tensile yield-point of the material and the tests were

carried to very high numbers of repetitions. Up to the present no "endurance limit" such as have been found for ferrous alloys has been found. Material from different shipments shows marked differences in number of repetitions that it will stand at a given stress, while in other tests (tension, tensile impact, cutting, hardness, etc.) they are comparable.

In the alternating flexural tests, special care has been found necessary to avoid vibration in the case of the thinner sheets. Unusually ingenious instruments and expedients have been devised in connection with this and the measurement of bending stress while the test is in progress.

Test of Limestone—Strength and time-load tests of Indiana limestone are in progress, with the co-operation of quarrymen, with a view to furnishing a basis for specifications for engineering and building use. In the

TESTING WALLS FOR FIRE RESISTANCE

Unexposed side of 8-in. solid Eastern surface clay brick wall at the end of the 6-hour fire test.

time-load tests it has been found that loads of one-half to two-thirds the ultimate do not produce progressively increasing deflections. An extensive series of tests of lifting devices is shortly to be undertaken. Waterproofing and prevention of stain are also under test.

Stucco Studies—A reinvestigation of the subject of wall stucco is being started, using different reinforcement and methods of support for the stucco. All the material is portland cement stucco; the foundations are metal lath of various types on wood frame with and without sheathing. A large number of panels are to be exposed. The work is carried on in co-operation with cement, lumber and metal lath and fabric manufacturers.

Cement and Alkali—A detailed field examination of samples of cement and concrete exposed in alkali loca-

tions during ten years is now in progress, and the results should soon be known.

Related questions are under study in connection with sewer pipe troubles reported from a Western city. Both clay and cement sewer pipe are included in the investigation. Trouble seems to localize at manholes, and to be in direct relation to the amount of hydrogen sulphide present. Brick sewers shown similar mortar trouble.

Alumina Cement—Various high alumina cements are to be made this year and exposed to alkali and sea water. Georgia bauxite will be used in manufacture.

Test Methods and Instruments—Two interesting studies of tests for metals are in progress. The Humphrey method of testing notched test specimens by slow bending is being compared with the Izod impact method, and different methods of carrying out the Brinell hardness test are being studied. One of the questions of great practical importance in connection with the Brinell test is method of determining the hardness of material when in thin sheets.

A highly sensitive optical extensometer and a distant-reading extensometer using the principle of the varying resistance of a set of carbon disks were developed at the Bureau during the past year and have been described recently (*Engineering News-Record*, Aug. 16, 1923, p. 266). The optical extensometer is to be applied on a large scale to the Navy tests of riveted joints, above mentioned, some thirty instruments having been made for this test series. The carbon-resistance extensometer has been used in stress measurements on the Navy's great dirigible ZR-1.

Fire-Resistance Tests—Walls built of clay, sand-lime and cement brick have been tested under fire exposure and fire and water exposure, in 11 x 16-ft. panels, with exposure on one side up to 6 hr. The present indication is that an 8-in. solid wall will stop the progress of severe fire, though it will crack and deflect considerably. Where combustible members are framed into the wall they decrease the fire resistance. The 12-in. wall has been proved adequate for all fire conditions likely to occur in buildings although heavier thicknesses may be necessary from the standpoint of strength and stability. A number of hollow walls have also been tested, and it is concluded that when filled at the floor line around ends of combustible members they are adequate for moderate exposures.

Fire tests of panels of hollow tile are in progress on an equally large scale. The fire resistance of walls, 8 to 12 in. thick, has been found to depend on the mineral characteristics of the clay. Thickness of shells and design are also factors. Fire resistance is increased by plaster coatings that remain in place. Repeated freezing tests indicate advantage for tile having low porosity. Load tests of the panels are also to be undertaken.

Strength at High Temperatures—Tests have begun on the compressive strength and elastic properties of materials at temperatures up to 1,000° C. Structural steel begins to decline in strength decidedly beyond 400° C. and fails under working loads between 550° and 650° C. Timber loses one-half or more of its strength at 100° C., and further rapid loss occurs beyond 150° C. Where actual failure and distortion of shape has not occurred, both steel and timber recover their strength almost completely on cooling. The rate of expansion of steel increases with temperature to values

more than one-half greater than obtain at ordinary temperatures; the maximum expansion under load approximating working loads in buildings is reached at about 500° C., where the yielding due to the load more than balances the expansion.

Fire Tests of Concrete Columns—A report is soon to be made on the results of about ninety fire and load tests of concrete columns made at the former Pittsburgh station of the Bureau. The tests showed the great effect of composition of aggregate: high-silica material gave the lowest resistance, and calcareous aggregates the highest, while trap rock and slag gave intermediate resistances. Fire resistance was increased by molded and plastered protection, and by metal binder in the outer protective concrete. There was little difference between round and square columns or between vertically and laterally reinforced columns, although the tendency to separate on the plane of the reinforcement was more apparent with the latter type.

Fires in Buildings—To give information on the probable maximum intensity and duration of fires in buildings, tests have been made in a one-story brick and concrete building 16 x 30 ft. fitted up as an office, finished with different types of floor, and burned out. The results are compared with evidence given by melted metal and other fire effects in the ruins left by actual fires. Very tentatively, the tests so far indicate that buildings housing office occupancies may be subject to fire exposures equal to the first hour of the standard fire test.

Building Exits—Investigation is being made of structural conditions, exit facilities, and safety devices concerned with securing safe exit of occupants of buildings. The safety of motion picture projectors and booths has been examined, fire tests have been made of theater proscenium curtains and curtain materials. Rigid structurally framed steel curtains have been tested, and tests of flexible asbestos curtains are in progress. The latter investigation indicates that a rigid curtain designed for a lateral load of 10 lb. per square foot of proscenium opening and protected on the stage side is effective in preventing the passage of flames, smoke and dangerous temperature to the auditorium side in the time required to empty the building, with a considerable margin of safety. Its operation can be made reliable and positive under all probable fire conditions. The investigations of the flexible curtain are expected to reveal the extent to which the same performance can be given.

Fire Tests of Roofing—The fire hazard of common roofing materials is under study in a series of brand, flame and spread tests, recently begun, covering wood shingles, prepared roll roofing and shingles, and eventually metal, slate and tile. Various sizes of brands are used, with different wind velocities over the test deck produced by a propeller fan. Brand tests will also be made in connection with hot blasts representative of conflagration conditions. The sample roofs are seasoned in ovens and under ordinary room conditions. It has been found that there is a considerable difference in the flammability between oven-dry and air-dry samples of wood shingle roofing, for which reason care will be used in approximating the conditions of practice. Tests will also be made of samples of shingle and prepared roofing from old roofs weathered for years.

North Carolina to Build a State Railroad

AN UNUSUAL project now under engineering investigation is the construction by the State of North Carolina of a railroad across the Blue Ridge in the northwestern corner of the state to give a new trunk line to the west. This railroad, in connection with existing lines, will provide a direct route from the central and eastern parts of North Carolina to Cincinnati, Ohio, and the Middle West, passing through coal fields of eastern Tennessee and southeastern Kentucky, which will thus be given an outlet to the east through North Carolina. The new line will also provide communication with four northwestern counties (Alleghany, Ashe, Watagua and Avery) which are shut off from the rest of the state by this branch of the Appalachian range. These counties, known colloquially

subscribe 51 per cent of the cost of such extensions the state will furnish the remaining 49 per cent.

Heavy construction work and considerable tunneling will be required. Three passes under investigation are Roaring Gap on a route between Elkin and Sparta; Daniel's Gap between North Wilkesboro and Jefferson; and Deep Gap, between North Wilkesboro and Boone. Both Elkin and North Wilkesboro are on a line of the Southern Ry. running west from Greensboro and Winston-Salem, N. C., and terminating in the foothills. By any route the new line will be at least 75 miles in length. The passes mentioned are at an approximate elevation of 3,200 ft., which is that of the tableland on the west side of the range, while the general elevation of the country in foothills on the east side is about 1,500 ft. The grades are not to exceed 1 per cent (compensated) against eastbound traffic and 1½ per cent (compensated) against westbound traffic. Curvature is not to exceed 8 deg.

The work of the special commission is now more than half completed and it is expected that by next summer the board of directors will be called upon to organize and proceed with construction work. The surveys and preliminary work are in charge of Frank T. Miller, Greensboro, N. C., as chief engineer for the special commission and for the railroad.

WHERE NORTH CAROLINA WILL BUILD A STATE RAILROAD

The proposed railroad is to give the state a new western outlet and to connect the eastern section with northwestern counties now isolated by the Blue Ridge. The route has not been established but the crossing of the ridge will be probably from Elkin to Sparta, North Wilkesboro to Jefferson or North Wilkesboro to Boone.

as the "lost provinces," have no railroad connection with the main body of the state but two of them have railroad outlets to the west. The situation is shown by the accompanying map, in which all railroads are of standard gage with the exception of 3 ft. gage for the Linville River R.R. and the East Tennessee & Western North Carolina R.R. The Laurel Fork R.R. is operated for freight service only.

Since the proposed railroad will be of great public benefit but is not likely to be undertaken by private enterprise, the North Carolina legislature at its 1923 session enacted a law authorizing the construction by the state of a railroad across the Blue Ridge to be known as the Appalachian & Western North Carolina R.R. This law constituted a special commission in charge of the project and appropriated \$50,000 for its use in determining by surveys and other investigations the best route for the railroad. The law also appointed individual members of the legislature to comprise the board of directors to organize the Appalachian & Western North Carolina R.R. Co., through which medium the construction and preliminary operations of the railroad will be carried on without the aid of the outside capital.

For the construction and equipment of the line, the law provides for a bond issue of \$10,000,000 which is equivalent to a direct appropriation. The state will hold all the stock of the railroad company and will pay the entire cost of construction. To assist in the extension of existing short lines to connect with the new railroad, the law provides that if outside interests will

Recording Road Maintenance Costs by Gantt Charts

Foremen's Field Report Made Simple—Computation and Charting Done in Office—Federal-Aid Costs Segregated

By H. J. FRIEDMAN

State Highway Department of Georgia, Savannah, Ga.

IT IS REQUIRED by the Bureau of Public Roads that data be kept on the cost of maintenance of federal-aid highway projects. These projects are comparatively short and it is necessary that separate costs distributed under various heads be kept on each. The method here worked out correlates the data necessary for federal-aid project maintenance costs, with various other highway maintenance costs, so as to secure figures which enable the engineer to draw the necessary conclusions for successfully directing the entire task of maintenance that falls within his jurisdiction. Incidentally this method of keeping cost data is that in use in the Georgia Highway Department division office at Savannah. It is here that cost data are assembled to the point where figures by counties or by projects are secured. The remaining work of applying the central office overhead and summarizing results for the state, is routine, and is not considered.

FIG. 2—DAILY REPORT OF TRACTOR OPERATION

Since figures on direct charges are turned in, in most cases, by foremen, who naturally are not accountants or engineers, a system of applying code numbers to the distribution of accounts, or any similar system, is not considered practicable. Also in the matter of indirect charges, such as repair parts for equipment, it is not practicable to make an office or field distribution on each bill, as there are too many projects or counties to which each item must usually be distributed. The system described permits the proper distribution of direct charges by foremen without code numbers or excessive mental effort, and also provides a simple method of pro-rating the indirect charges in proportion to the actual work done on each project or unit considered.

It is best to have one person, preferably the office engineer, who will hereafter be referred to as the cost accountant, handle and be responsible for the maintenance cost data. He should work up his data from information and reports furnished by the division cashier, maintenance supervisor and foremen. It is necessary that cost data be summarized in such shape that the information is in compact form and adapted to ready comparison. The Gantt chart is believed to be the best medium for this.

Maintenance cost data should cover the following phases of work:

1. Cost and performance on truck and tractor operations.
2. Cost of maintenance of completed federal-aid projects.
3. Costs, as compared with allotments, by counties or divisions.

Maintenance foremen keep a daily record, Fig. 1, covering the operation of their trucks, which is turned in to the division office the last of each month. This report covers the cost of gas, oil and grease, and mileage covered. The data for each truck are plotted on a Gantt chart similar to that in Fig. 3. The item of repairs is a difficult one for the foreman to determine, as he orders parts from the division office for which he does not see the bills. This item as plotted by the cost accountant is secured from the records of the division cashier. Maintenance patrol cars are handled in the same manner as trucks.

Foremen also turn in a daily tractor report on the form shown by Fig. 2. This shows mileage covered and gas and oil consumed. It is necessary to consolidate these figures for each month's operation under the heads gas and oil, and mileage. The item repairs, as in the case for trucks, is best secured from the records of the division cashier. The results are plotted on a Gantt chart similar to Fig. 3.

A report is required of each foreman for each federal-aid project he works on, on any day. On this report in addition to the time of his force and its distribution, a statement is made of the mileage run by trucks and tractors, respectively. The cost account-

	Cost per month Gas and oil	25	25	25	25	25	25				
	Cost per month Rep. and tires	25	25	25	25	25	25				

FIG. 3—TYPICAL GANTT CHART RECORD OF TRUCK OPERATION

ant enters these charges as on form Fig. 4, also noting the mileage run by trucks and tractors. At the end of the month these charges are footed. From the division cashier, the total division maintenance overhead charge is secured and pro-rated on a mileage basis to each project, under the charge division overhead.

The mileage run by each truck and tractor is reduced to a money charge and these charges, properly distributed, are shown below the footings. These charges are secured with the use of the charts, and the method is best explained by a concrete example.

Ford truck No. 674 was run 64 miles in connection with tractor operation on F.-A. Project 47, Screven County, during the month of June. The chart indicates that during June, truck No. 674 ran 1,160 miles at a cost for repairs, gas and oil, of \$83. Then the charge against F.-A. 47 is 64/1160 of \$83, or \$4.60.

It is realized that this is not an exact figure. How-

Specimen "D" FEDERAL-AID PROJECT COST SHEET

July 1922	233-675	181	64	6				6	45	270	24	1	6.60	276.60
Total to date														

FIG. 4—FORM FOR FEDERAL-AID MAINTENANCE COST SHEET

over, the result is well within the limits of accuracy to which the foreman can distribute his charge to the project.

The truck and tractor charges are entered below the monthly footings (which represent the direct charges and the overhead charge). A total is then struck, which represents the amount expended for the month under the different heads.

The figures secured take into consideration all costs except central office overhead and depreciation and interest charges on equipment, which should be applied from the central office on a pro-rata mileage basis.

Costs as compared with allotments by counties or divisions are obtained from the division cashier and plotted as a Gantt chart similar to Fig. 3. It is necessary to make a schedule for costs per month and of mileage on which the chart is based. This is done from data on hand from past performance. If, after the chart is under way, performance shows a wide variation from schedule, the schedule may be changed at any point on the chart without difficulty.

Rochester Compares Three Types of School Buildings

Different Designs for Buildings of Similar Dimensions—Cost of Fireproof Construction Compares Favorably with Fire-Resisting Construction

By A. R. REILLY

Structural Engineer, Department of Buildings, Board of Education, Rochester, N. Y.

THE THREE types of buildings for which separate drawings were made recently by the Board of Education of Rochester, N. Y., furnish a basis for interesting studies of schoolhouse construction. Each of the three sets of drawings calls for a two-story building with accommodations for the same number of children.

Official bids were received by the board as follows:

	Cubage	Total Amount of Low Bids	
		Without Addition	With Addition
Design No. 1	1,245,917	\$411,577 50	
Design No. 2	1,245,917	435,252 01	\$513,016 41
Design No. 3	1,306,265	444,187 70	581,334 15

Design 1—wood joists and floors in classrooms, with fire-resistive construction in corridors, stair halls, and toilet rooms; exterior and interior walls brick bearing; hollow gypsum tile partitions between classrooms and around flues; steel beams spanning classrooms transversely at the center of rooms and under gypsum partitions; No. 24 gage "tin pan" concrete slabs for corridor floors; roof over corridors as well as classrooms of wood construction; excavation of approximately 5 ft. under the entire first floor, which space is used for steam and hot air pipes to keep the floor warm in winter.

Design 2—is reinforced-concrete skeleton supporting walls and floors; exterior walls of hollow clay tile veneered with face brick; interior partitions hollow gypsum tile except in stair towers which are enclosed in solid gypsum tile; assembly hall structural steel skeleton with fireproofing of hollow gypsum tile and brick; one-way gypsum tile floors; excavation under entire first floor similar to design 1.

Design 3—an embodiment of ideas of a consulting architect who was employed by the city of Rochester

to suggest some means by which the cost of school buildings might be reduced—brick bearing exterior walls with a reinforced-concrete skeleton supporting the interior, except the assembly hall which is similar to design 2; intermediate column along the corridor side of classroom; first floor laid directly on the ground with a space for pipes in the attic and concrete plenum chambers below first floor for ventilation.

All reinforced concrete of designs 1, 2, and 3 is designed in accordance with the Joint Committee Rulings of July 1, 1916, with a few exceptions which are considered ultra conservative. The live-loads of 70 lb. per square foot for the classrooms and 100 lb. per square foot for assembly halls seem excessive according to the growing opinion on the subject. However, this department has made a study of the effect of the physical exercises carried on in our classrooms and assembly halls and is convinced that school buildings should be designed to safely carry these loads.

Although the light No. 24 gage tin-pan slabs were called for in the corridors of design 1, it is considered that this type of construction is not good. The pans collapse under ordinary pouring conditions, allowing concrete to run in on metal ceiling lath, increasing loads allowed for in the design, wasting concrete, giving variations in joist widths and fireproofing, and very often causing honeycomb conditions. However, the heavier cross-ribbed pans were allowed to be quoted upon for designs 2 and 3. In many cases the metal ceiling lath used in connection with tin-pan construction is subject to considerable corrosion before plaster is applied.

Floor Construction—Contractors were allowed to quote two-way tile floors as an alternate in designs 2 and 3. Although the figure on 3 was not as favorable as on 2, the reason is very evident. The slabs, having no restraint and only simple bearing at exterior walls, require an additional moment factor, involving thicker slabs and heavier reinforcement. The figure for two-way tile floors on design 2 was not received with formal bids.

There is a question in the minds of some engineers as to the advisability of reducing moment factors as suggested by the Bureau of Standards Report 220, but as the United States Bureau of Standards considers this type of floor construction safe and as we know structural formulas are theories proven empirically, there is no reason to doubt the safety of such floors. Economy is good engineering. The history of flat-slab design offers a precedent. As the system lends itself to light loads and panel dimensions of school construction, the girders along peripheries give a better distribution of loads to columns than the one-way systems, thus reducing the unbalanced moments transmitted thereto. The tie-through gives structural unity. The saving of plaster and simplicity of forms appeals to the contractor.

The intermediate column added along the corridor side of classrooms in design 3 is governed in minimum diameter by the height rather than economic design as in 2. Column forms cost more per square foot than beam forms. This, together with the saving of floor space by omitting the intermediate column, effects an additional economy of \$1,200 by using design 2.

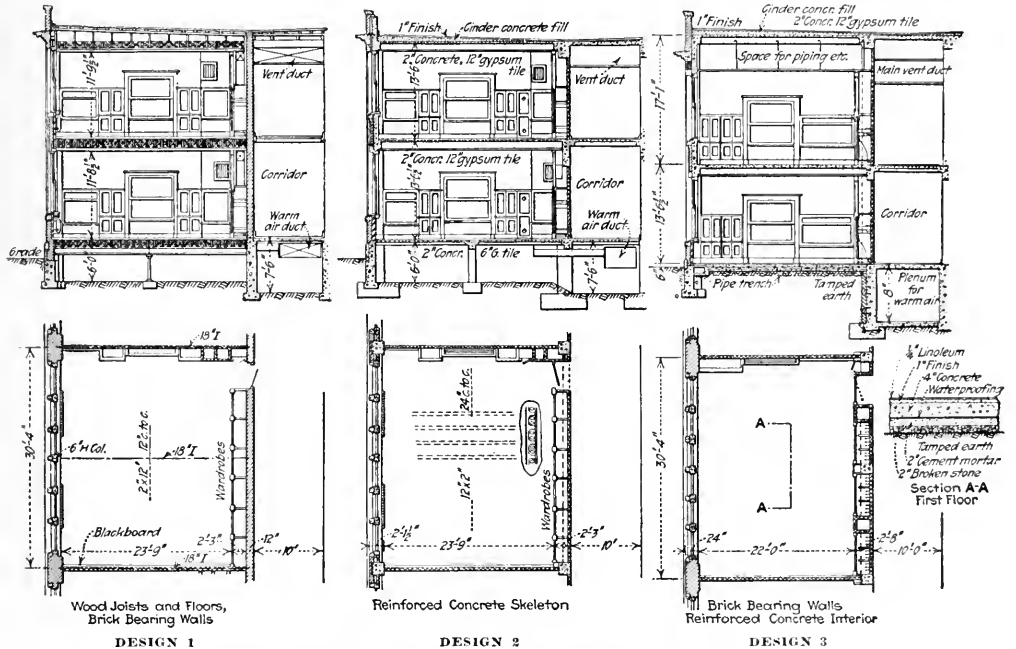

Most of the masonry contractors have enthusiastically approved of design 2 because it is possible to

complete the concreting operation before bricklayers are needed on the job. In the past it has been a piecemeal proposition involving laying off and re-employing men. It is also less expensive to lay up a 4-in. brick veneer with 6-in. hollow tile backing than a 12-in. solid brick wall. The heat loss through the former is less.

The first floor system of design 3 as indicated below, being laid directly on the ground, is not good construction. Experience has taught us that it is not only cold and damp underfoot but unsanitary. No precaution of preparation of foundation and waterproofing of strata will give to subsoil a uniform settlement. Cracking is bound to result and rotting of wood sleepers and flooring, or linoleum as the case may be, will cause a higher maintenance cost. Placing the floor on the ground requires that space for piping be furnished above the second story ceiling, which ceiling had to be

	Without Addition	With Addition		N. E. A.
	Design 1	Design 2	Design 3	Average
	Per Cent	Per Cent	Per Cent	Per Cent
Walls and partitions.....	7 10	6 80	6 94	10 00
Flues.....	1 80	1 75	1 54	3 00
Corridors and stairs.....	22 70	20 15	22 02	20 00
Accessories.....	0 00	0 00	0 00	1 00
Instruction.....	54 70	59 00	55 00	50 00
Administration.....	13 70	12 30	14 50	16 00
	100 00	100 00	100 00	100 00

Much could be said about maintenance and more thought should be given to it. The first design is not the structural unit that the second is, so naturally more unequal settlements and cracking of plaster, brick-work, terrazzo, and tile work can be expected. The third, with its first floor on the ground and its exterior bearing walls lacking the "tie-through" of the second, will have unequal settlements. The fire hazard in the first is much greater than in the other two, and the spending

COMPARATIVE DESIGNS OF SCHOOL BUILDINGS FOR ROCHESTER, N. Y.
Typical plan and cross-section of three buildings differing only in structural details.

designed to carry a live-load for the repairing of pipes. Metal ventilation ducts in the excavated basement of design 2 had to be replaced by concrete plenum chambers in 3. In the latter, cross branches and conduits required concrete trenches under the first floor slab. The attic of design 3 naturally involves a higher building and more exposed wall area.

Division of Floor Areas—It should be noted that design 3 calls for a reduction in the width of classrooms from 23 ft. 9 in., Rochester's standard, to 22 ft. 0 in. Wardrobes are within the rooms along the corridor side. "The Candle of Efficiency" as published by the Committee on Standardization of School Buildings of the National Education Association was applied to all three designs. The following table shows the division of floor areas in percentages according to the above named standard:

of an additional \$2,500 to complete the sprinkler system in it would further reduce the difference in cost between design 1 and design 2.

The figures received indicated that 85 per cent (\$58,100) of the economy of design 2 over 3 was in the masonry work. The heating, electrical, and plumbing figures showed an economy for design 2 over 3 of approximately 3 per cent, plus the cost of ventilating ducts of design 2. This was largely due to the fact that the exposed wall area of the former is 8,300 sq. ft. less than in the latter. The saving is slightly offset by the better facilities for piping and conduit work in the attic of design 3.

Although it is not prudent to draw definite conclusions from isolated cases, yet the economy of a reinforced-concrete skeleton for school buildings is so positive that it should appeal to the structural engineer.

The 8-M.G.D. Sioux Falls Iron-Removal Plant

One of the Largest Iron-Removal Plants. Built at Low Cost, Has Small Hand-Operated Units and False Bottom Underdrains

BY F. G. GORDON

Principal Assistant Engineer, with Dabney H. Maury,
Consulting Engineer, Chicago

STRICT economy dictated the use of several of the more unusual features in the new 8-m.g.d. iron-removal plant at Sioux Falls, So. Dak., built at a cost of \$11,125 per million gallon capacity. Small filter units permitted hand operation of the valves. Recording water-level gages on the filter effluent line replace the ordinary integrating loss-of-head gages. A spent wash-water storage sump spreads out the discharge so that a smaller drain answers. The underdrains consist of a steel plate false bottom, into which nozzles are screwed.

Before preparing final plans an experimental plant was operated to determine whether aeration, followed by sedimentation and filtration but without the use of chemicals, would remove the iron satisfactorily. As the results with the experimental plant indicated a 96 per cent removal, it was decided to employ this process in the contemplated plant.

The water supply is obtained from large shallow wells sunk in an excellent gravel stratum located in the Big Sioux River valley. From these wells the water is lifted by motor-driven centrifugal pumps to the aerator in the iron-removal plant. The aerator is of the weir-step type, in which the water cascades down concrete steps on which removable 1½-in. pipe are placed to break up the stream. From the aerator the water flows into one end of the sedimentation basin and is collected at the other end by an overflow weir, from which point it passes to the filters.

There are sixteen filter units, each having a capacity of 500,000 gal. per day when operating at a rate of 125 m.g.d. per acre. The use of units of this size was influenced by operating conditions and by structural reasons. It was expected that, from the standpoint of

FIG. 2—DETAIL OF FILTER NOZZLE

having larger units. The iron-removal plant was built directly over an existing reservoir, in which the column spacing and design combined to make advantageous the construction of filter units of the size used. Certain iron-removal plants in the past have experienced difficulty with a growth of crenothrix in the sand. It was thought that the use of the smaller units would enable the handling of such difficulties (if they occurred) more easily than in units of larger size.

Each filter unit has 30 in. of sand and 15 in. of gravel, the gravel resting on a ½-in. steel plate which is supported by short cast-iron columns. The gravel was screened to size and deposited in the filter in the following layers:

Thickness of Layer	Size of Gravel
5 in.	2 in. to 1 in.
2 in.	1 in. to ½ in.
3 in.	½ in. to ¼ in.
2 in.	¼ in. to ⅛ in.
2 in.	⅛ in. to size passing No. 10 sieve

Specifications called for a sand having an effective size of from 0.35 to 0.50 mm., and as low a uniformity coefficient as possible. The steel plate which serves as a false filter bottom is drilled and tapped on 6-in. centers to receive ¾-in. brass nipples, to which cast-iron umbrella-shaped nozzles are screwed. The design of these nozzles was based on those used by the American Water Works and Electric Co. in its East St. Louis plant. The area of the openings through the brass nipples is 0.53 per cent of the total area of the filter bed. The area of the openings through the nozzles is in excess of the area of nipple openings. The distribution of wash-water is apparently very uniform.

A new type of rate controller manufactured by the International Filter Co. was used in this installation. This controller is of the Venturi type, with a butterfly valve operated by a diaphragm. Tests, in which the head on the inlet side was varied from 2.5 to 5 lb. in an interval of one minute, showed a variation in discharge of less than 5 per cent.

Recording water-level gages were used for loss-of-head gages. The gages for adjoining filters were mounted back to back on 1-in. gage boards located on the operating floor. Although this type of gage is not differential in its action, it gives a satisfactory record because the water level in the filters is carried within a few inches of the same elevation at all times.

Since a single wash-water pump is provided, for emergency use a connection is made to one of the high service mains leading from the pumping station to the distribution system. The friction loss through this connection was carefully calculated, and the size of the pipe selected so that the wash-water pressure when delivering a sufficient quantity for washing purposes would not be excessive.

A sump having a capacity of 40,000 gal. was con-

FIG. 1—STEEL PLATE FALSE FILTER BOTTOMS

hand operation which had been decided upon, it would be easier to operate the valves for the plant as designed than to operate the fewer but larger valves of a plant

structed to receive the wash-water from the filters. The construction of this sump permitted the use of a 10-in. cast-iron drain from the sump to the nearest city sewer instead of the 16-in. drain which would have been required if the sump had not been built. The saving due to the use of the smaller drain amounted to \$5,887, while the cost of the sump was only \$1,617. Cast-iron construction for the drain was necessary because of its proximity to the gravel stratum from which the water supply is obtained. The Champaign and Urbana Water Co. has had a similar arrangement in

The office, laboratory and pump room are located at the front of the filter plant building. The pumping equipment, which is all motor-driven,

consists of a wash-water pump, three auxiliary low-lift pumps, which can be used as boosters to assist the well pumps during the periods of low ground water, and one high-service pump.

The concrete used in the filter tanks and in the walls of the sedimentation basin consisted of one part of cement to five parts of coarse and fine aggregate. In determining the proportion of fine to coarse aggregate, sieve analyses were made of both classes of material. The theoretical proportions first adopted were those which would give a smooth curve of parabolic form when the quantity of material passing the various sieves was plotted. It was found, however, that a more plastic concrete could be obtained by the use of slightly more fine aggregate and less coarse aggregate than the theoretical curve indicated. The slump test was used to con-

trol the amount of water in the concrete. Concrete was mixed for 1½ min. after all ingredients had entered the mixer and was placed with two-wheel carts. As the concrete for the walls of the sedimentation basin was deposited during the winter, the materials and water were heated and the concrete placed in forms which were protected by heavy straw mats on the weather side. Salamanders were used on the interior.

No trouble was experienced in putting the plant in operation, and operating results up to the present time have been entirely satisfactory. The raw water has an

iron content of 4 to 5 p.p.m., while the filtered water shows 0.15 p.p.m. A greater reduction in the iron content of the filtered water will probably be obtained when the most desirable rate of wash, quantity of wash-water and time for washing have been determined. At the present time the amount of wash-water used is about 2 per cent of the amount of water filtered. The filters are washed at a rate which gives a 24-in. vertical rise per minute.

John Mundt, the commissioner in charge of the Sioux Falls Water Department, through persistent advocacy of the plant over a period of years, was largely responsible for its construction. The plant was designed in the office of Dabney H. Maury, consulting engineer, Chicago. The resident engineer was Paul G. Windt.

Minnesota Drainage Work Is Slack

Land drainage activities in Minnesota during the year ending June 30, 1923, were at a low ebb. According to a statement by E. V. Willard, commissioner of the State Department of Drainage and Waters, this slackening in the reclamation of wet and overflow lands was due to three years of abnormally low precipitation combined with the poor economic situation among the farmers. Revival of drainage work in the past few months indicates that prosperity is returning, particularly in the southern part of the state, but it will take a year of heavy rainfall to restore normal activity.

Studies in Highway Traffic and Finance

Abstracts of Committee Reports to the Advisory Board on Highway Research of the National Research Council, Presented at Meeting in Washington, Nov. 8-9, 1923

Sources and Expenditure of Highway Funds

By J. G. McKay

Bureau of Public Roads, Washington, D. C.

BEFORE decision as to the justice or expediency of methods of highway financing, it is necessary to make a complete study of the sources of highway revenue, local, county, and state, in typical states. Most previous investigations have been limited to a study of the sources of state revenue for highway purposes and have disregarded the county and local expenditures. The following results are based on an analysis of all sources of revenue and expenditures in four Wisconsin counties from 1915 to 1921. Wisconsin was selected as a state whose system of highway financing represents a fair average of methods of raising highway revenues in other states. The counties were selected as representing the highway development in different sections of the state.

Dane County is a well populated, rich agricultural county, with no highway bond issues. Madison, the capital city of the state, is located in the center of this county.

Outagamie County is a good agricultural county. It has financed a large portion of the construction of its highway system through bond issues since 1916.

Rusk County is located in the newer section of the state. It is a purely agricultural county with soil of average fertility but as yet largely undeveloped. No highway bond issues have been made and its highways are, with the exception of the state trunk highways, largely unimproved.

Waukesha County lies west of the city of Milwaukee and is a rich dairying and manufacturing county. It has floated large bond issues during the past three years.

Table I shows the total expenditures for highways in each county. It is evident that the proportion of the burden of all highway expenditures which rests upon real property

portion of revenue for highway expenditures. It will be noticed that real property taxation and "other revenue" taken together furnish almost the same proportion of revenue for highway expenditures in all counties. The figures are as follows:

	Per Cent
Dane County	76.82
Outagamie County	79.86
Rusk County	81.35
Waukesha County	78.68

A comparison of the proportions furnished by each source of revenue in any one county for the different years substantiates the conclusion that the contribution of real property varies inversely as the contribution of other revenue. Other revenue as the name indicates is made up of all sources of revenue except the sources listed separately in Table I, but the principal part of it is made up of revenue derived from the income tax. The other sources of revenue included under this head such as fees, fines, etc., form a very small proportion of the total in this class. The annual expenditures by counties from each source of revenue show that in the years 1917 and 1918, when the receipts from

TABLE II—PERCENTAGE OF TOTAL REVENUES FOR HIGHWAY EXPENDITURES RAISED BY VARIOUS GOVERNMENTAL UNITS

County	Local Funds	County Funds	State Funds	Federal Funds
Dane	41.27	32.81	20.54	5.38
Outagamie	34.88	49.63	12.01	3.48
Rusk	48.20	30.37	15.36	6.07
Waukesha	39.56	29.55	21.76	9.13
Average	40.98	35.59	17.42	6.02

the income tax were highest, the proportions of revenue derived from real property taxation were smaller than in the years when the receipts from the income tax were smaller.

Table II indicates the importance of funds raised by the local units (townships and villages) for highway purposes, as compared with state and federal funds. The funds raised by the local units and counties furnish from 69 per cent to 84 per cent of the total highway expenditures. While this analysis is based on only four counties it is safe to assume that these proportions are reasonably correct for the state of Wisconsin as the counties studied were selected as representative of the various counties within the state. In other states the proportion raised by the various governmental units may vary to a considerable extent from those shown in Table II, but in those states which are organized on the township basis the funds raised by the local units and counties will approximate the percentages shown in Table II. The percentages shown in Table II are derived from the total expenditures within the different counties for the period 1915 to 1921 inclusive. It should be noted that this period includes a few years before the period of federal aid, and also that the activity of the state in the highway field has increased greatly during the later years so that had the period been made to include only the years 1918 to 1921, the percentages derived from state and federal funds would probably have been larger.

The proportions of highway expenditures contributed by local, county, state and federal units, as indicated in Table

TABLE I—PERCENTAGES OF EXPENDITURE FOR HIGHWAYS IN FOUR WISCONSIN COUNTIES

	Total	Local	County	State	Federal
<i>Dane County</i>					
Total	100.00	100.00	100.00	100.00	100.00
Real property taxation	60.29	74.06	66.99	37.73
Personal property taxation	11.20	12.06	17.14	8.71
Other revenue	16.33	9.47	19.26	4.50	100.00

Special assessments	1.82	4.41
Miscellaneous contributions	0.08	0.24
<i>Outagamie County</i>					
Total	100.00	100.00	100.00	100.00	100.00
Real property taxation	63.27	66.57	71.82	36.67
Personal property taxation	13.54	12.52	17.14	8.71
Other revenue	16.59	20.53	11.04	3.95	100.00
Automobile license fees	6.12	50.97
Special assessments	0.48	1.38
<i>Rusk County</i>					
Total	100.00	100.00	100.00	100.00	100.00
Real property taxation	69.83	82.04	81.68	35.70
Personal property taxation	10.23	10.17	13.48	8.07
Other revenue	11.32	7.46	4.84	2.73	100.00
Automobile license fees	8.26	53.76
Special assessments	0.16	0.33
<i>Waukesha County</i>					
Total	100.00	100.00	100.00	100.00	100.00
Real property taxation	55.29	64.18	72.88	38.45
Personal property taxation	10.19	10.59	13.90	8.70
Other revenue	23.39	24.66	13.22	2.73	100.00
Automobile license fees	10.90	50.12
Special assessments	0.23	0.57

varies from 55 per cent to 70 per cent. The highest proportion is found in Rusk County, relatively undeveloped, while the lowest proportion is found in Waukesha County, a very rich section both agriculturally and industrially. This variation is due largely to differences in revenue derived from the income tax. In the richer counties the income tax furnishes a larger portion of the total revenue, and as a result, insofar as funds for highway expenditures are taken from general revenues, the income tax furnishes a larger

TABLE III—PERCENTAGE OF TOTAL REVENUE FOR HIGHWAY EXPENDITURES FROM REAL PROPERTY TAXATION LEVIED BY VARIOUS GOVERNMENTAL UNITS

County	Local Taxation	County Taxation	State Taxation	Federal Government	Total
Dane	30.56	21.98	7.75	60.29
Outagamie	23.22	35.64	4.41	63.27
Rusk	39.54	24.81	5.48	69.83
Waukesha	25.39	21.54	8.36	55.29
Average	29.68	25.99	6.5	62.17

II, may vary to a considerable extent in different localities, nevertheless the figures are conclusive evidence that any discussion of highway finance which treats exclusively of state and federal expenditures, omits local and county expenditures which constitute the major portion of the total highway expenditures. While it would be advantageous to have more of our highways entirely financed and constructed by the state, the fact remains that at the present time local and county highway expenditures absorb the major portion of funds raised from all sources for highway improvement.

While the general property tax is the most important single source of revenue for highway expenditures in all units—the townships, the county and the state—its importance as a source of highway revenue is much greater in the township and county than in the state. As will be noted from Table III real property taxation by the local units furnishes from 23 per cent to 39 per cent of all highway expenditures, and county real property taxation provides

TABLE IV—PERCENTAGE OF REAL PROPERTY REVENUE FOR HIGHWAY EXPENDITURES LEVIED BY GOVERNMENTAL UNITS

County	Local	County	State
Dane.....	50.70	36.45	12.85
Outagamie.....	36.70	56.33	6.97
Rock.....	36.62	35.52	7.86
Waukesha.....	45.93	38.95	15.12
Average.....	47.49	41.81	10.70

from 21 per cent to 35 per cent of the total highway expenditures, while state real property taxation provides only from 4 per cent to 8 per cent of the total highway expenditures.

Table IV shows the proportion of real property taxation revenues for highway expenditures raised in each county by the various units. An average of 47.49 per cent is raised by the local units, 41.81 per cent by county units and 10.70 per cent by the state. *The real property revenue for highway expenditures raised by the state in comparison with local and county real property revenues is but a small share of the total real property revenue raised for highway improvement.*

It is to be noted that real property taxation produces seven times as much of the total highway revenue as that derived from motor vehicle license fees, while the taxation of incomes (other revenue) produces approximately double the amount raised by vehicle license fees. Since local funds are expended on purely local roads, it is fair to compare the amount of county and state real property tax funds produced for expenditures on state and county highways with the amount raised by vehicle license fees used on the same highways. County and state real property taxation produce 32.49 per cent of total highway revenue, vehicle license fees 8.84 per cent. Real property which contributes 62 per cent of all highway expenditures produces for county and state highways four times as much of the total expenditures as that produced from vehicle license fees.

The conclusions based on this analysis of the sources and expenditure of highway funds in four representative Wisconsin counties are as follows:

1. The major portion of the total of highway funds in Wisconsin during the seven-year period from 1915 to 1921 was raised by township and county units rather than by the state.

2. Real property taxation was the chief source of highway revenue producing an average of 62.17 per cent of the total local county and state highway expenditures.

3. Vehicle license fees produce 8.84 per cent of the total highway expenditures.

4. Real property taxation for highway purposes bears too large a portion of the burden of highway expenditures, producing from 55 per cent to 70 per cent of the total highway revenue.

5. The major portion of the burden on real property is due to local and county taxation of real property for highway purposes. The local units produce 47.49 per cent, county units 41.81 per cent and the state 10.70 per cent of the real property revenue for highway expenditures.

6. Real property contributes a larger share of highway revenue during periods of depression, when the revenue from

TABLE V—SOURCES OF HIGHWAY REVENUE FOR TOTAL HIGHWAY EXPENDITURES

Source	Average	Percentage
Real property taxation.....	62.17	
Other revenue (largely income tax funds).....	17.91	
Personal property taxation.....	11.29	
Vehicle license fees.....	8.84	
Miscellaneous.....	0.69	

other sources decreases. This results in an excessive levy on real property owners since the tax levy on real property is paid from income derived from the property and in periods of low prices this income is reduced at least as much as income from other sources.

7. When income tax funds increase within a county, real property taxation for highway purposes decreases.

8. As a county develops and grows richer the relative burden on real property for highway purposes decreases. When a county or state is in the developmental stage the cost of the permanent features of highway improvements can be economically financed by issuing a limited amount of deferred serial highway bonds. By this method the burden on property is lightened during the early years of the improvement, increasing with the ability of property to produce more revenue as a result of the highway improvements.

9. A reduction or elimination of state taxation of real property for highway purposes in Wisconsin would not materially reduce the total of real property taxation for all highway purposes.

10. Reduction of real property taxation for highway purposes in Wisconsin would result largely in a reduction of local and county taxation of real property for towns' and highway expenditures.

Highway Traffic Analysis

By G. E. HAMLIN

Connecticut Highway Commission, Hartford, Conn.

IT IS necessary to differentiate between a highway traffic census and a highway transport survey. The traffic census will give information pertaining to the traffic using the highway at the time the census is taken and the purpose of the highway transport survey is to determine the probable amount and character of the future traffic which will use a given highway during the lives of its several component parts. Up to the present time, the information collected by the various states has given traffic census information and no state has extensively taken up the highway transport survey.

A highway traffic census is of value only for determining conditions which exist at the time the census is taken. It may be that by the construction of a new section of road the general trend of traffic may be radically changed in any particular locality. After an extended highway traffic census, it is recommended that additional counts be taken at critical periods of the year in succeeding years from which, after a number of counts have been taken, curves of natural increase can be plotted from which can be roughly determined an estimate of increased traffic for a reasonable period of years. This estimate should also include the curve of increase of motor vehicle registration which can be determined at the present time in every state. It is questionable if such a curve can be applied to other than the locality in which it is developed. In fact, even in a state of small area, different curves will have to be developed for different sections of the state, rather than to utilize a general curve for all of the main highways. Up to the present time it has been found impracticable with the data available, to develop a formula of this character.

The value of an extended traffic survey in determining the allocation of construction and maintenance funds in the development of a highway system is unquestioned. Such traffic survey, however, should be utilized for type and strength of surface, rather than for location of expenditures inasmuch as the development of new territory within a state is as much a demand upon the expenditure of highway funds as the taking care of traffic already developed. This

point cannot be stressed too strongly, for, if the allocation of funds depends wholly upon the volume of traffic, only a few of the roads in any particular state would ever receive a construction allotment. This is where the decision of the engineer in charge is valuable and this decision must be based on potential as well as present traffic conditions. In other words, he must minimize any particular locality to consider the value of transportation in the whole state and each construction unit must be based on his vision of the value of such unit.

To carry out a traffic survey successfully much planning must be done preliminary to the actual field work. Stations must be chosen which will give the average condition along each highway and these must be located at a sufficient distance from the congested centers to eliminate as far as possible the strictly local traffic which will not enter into the construction program. Care should also be taken to establish stations where traffic is divided so that the value of each section as well as each road may be determined. Each station should be occupied at least one day each month, for an eight- to twelve-hour period. This should be arranged so that the same station will be occupied successively on different days of the week and on a different hourly basis to determine daily as well as seasonal variation of traffic. Blank forms where check marks may be used will reduce the time required for gaining information and names of cities, character of loading and make of truck or car may be coded, thus simplifying actual compilation of office records.

In the state of Connecticut the cost of three parties operating over a year's period with varying numbers, including necessary automobile transportation, board allowance, etc., has been about \$27,000.

* * *

Motor Truck Transportation in New England

By J. G. McKay

Bureau of Public Roads, Washington, D. C.

THREE groups of agencies in New England are engaged in the transportation of people and commodities: steam and electric rail lines, boat lines, and highway transportation companies.

From September to December, 1922, over a million net tons of freight were transported by motor trucks over the Connecticut highway system. Rail service during this period was below par due to labor difficulties, and naturally this situation increased the volume of highway transportation above the normal level. The largest portion of motor truck net tonnage movement was limited to the short haul zone: 69.4 per cent was hauled less than 30 miles, 18.4 per cent from 30 to 69 miles, and 14.2 per cent over 70 miles.

Two factors are in general responsible for the highway transporting of commodities over 20 miles: (1) The lack of rapid and efficient rail service enabling shippers to obtain fast rail transportation of l.c.l. freight. (2) A limited number of commodities which are especially adapted to motor truck shipment and will probably continue to be shipped by truck for distances beyond the short haul zone. The total ton volume of these commodities is not very significant.

Since January, 1923, the per cent of the total net tonnage transported by motor truck beyond 30 miles has decreased, indicating that with efficient rail and boat service the motor truck is not a major transportation factor in the middle distance and long haul zone.

The commodities transported by motor trucks on the Connecticut highways reflect the industrial production of New England. Of the total net tonnage 73.6 per cent are manufactured goods, 8.5 per cent products of agriculture, 7.1 per cent of animals, 6.7 per cent products of mines and 4.1 per cent products of forests. The large per cent of manufactured goods is partly explained by the fact that more profit can be made in motor truck transportation of these goods than by moving bulky goods of lower value.

In general manufacturers ship their commodities by motor trucks for two reasons: (1) Prompt and reliable service and (2) Trade demands. Railroad freight congestion and rail embargoes force manufacturers to ship their products by motor trucks in both the short and the long haul zone.

A combination of motor truck and rail and motor truck and boat service is a modern development. This service has developed largely in response to the demands of shippers for a rapid pick-up and delivery service of freight. The motor trucking company assembles the commodities and loads the freight cars which are forwarded daily regardless of whether they are loaded to capacity or not. The cars are shipped by rail to destination and the trucking company unloads and delivers the freight.

The second type of joint service is a combination motor truck and boat service which has developed very rapidly in the past few years. In most cases this service is limited to over-night delivery from New England points to New York City. The Starrin-New Haven line operating between New Haven and New York City is the best illustration of this type of service. This company maintains a sidewalk pick-up and delivery from Derby, Shelton, Ansonia, Seymour, Beacon Falls, Naugatuck, Waterbury, New Britain, Meriden, Wallingford, Middletown and Hartford, Connecticut, to New Haven, Connecticut, and ships by boat from New Haven to all points.

Highway transportation of freight and passengers is increasing in volume each year. Its development has been so rapid and the information as to its movement is so meager that it is extremely difficult to lay down any definite principles as to the economic sphere of motor trucking companies engaged in the highway transportation of freight. The following is a tentative outline of the economic fields of motor truck transportation as a correlated part of our transportation system:

1. Organized urban motor truck transportation in congested terminal areas consisting of motor truck terminal to terminal freight transfers as well as pick-up to delivery service. This can be illustrated by the operation of the U. S. Trucking Co. in New York City in co-operation with the Erie R.R. in the transfer of freight from the Erie-New Jersey terminal to New York City for delivery. Carefully organized and efficiently operated motor trucking companies, assured of rail and steamship co-operation, will materially speed-up terminal freight movement, decrease the volume of freight warehoused, reduce the cost of moving freight through terminals and expedite the rail delivery time of l.c.l. freight.

2. The organization of motor truck freight service to supplement and extend existing rail and water transportation agencies. The development of motor transportation companies in areas inadequately served with rail or water transportation offers an enormous possibility for the economic extension of highway transportation. This type of service is especially desirable in the development of new areas or localities with insufficient transportation facilities and will make available additional tonnage for movement by rail or water. This is a non-competitive service extending and supplementing existing rail and water agencies.

3. The short haul transportation of freight probably not to exceed 30 miles. The freight transported by motor trucks in the short haul zone is largely a non-competitive assembly and distribution of commodities. The differences in the density of population in different areas, the distance between cities and areas of production and distribution, the prevailing type of production and the type of rail or water transportation available may decrease or increase the above zone of the short haul.

4. Motor truck transportation of a limited number of special commodities in the long haul zone in which delivery time, the character of the goods transported or the demands of the industry or trade, indicate the desirability of motor truck transportation. This type of freight is but a small percentage of the total net tonnage transported over the highways.

Through the Reclamation Country

By F. E. Schmitt
Associate Editor, *Engineering News-Record*

THIS is the ninth of the series of letters written by Mr. Schmitt during a journey recently made through the West in which he visited irrigation projects, studied developments, and interviewed builders, operators and settlers, in order to present to our readers the actualities of reclamation as revealed to an unprejudiced investigator.

The series of letters began in the issue of October 4.

Phoenix, Ariz.

MANY special views of reclamation are afloat in this great West. They appear peculiar to the visitor. Some of them are connected with past reclamation policy and some with future policy; many are related to what is often called the repudiation sentiment of the project farmers. A general appraisal of present reclamation difficulties is bound to encounter them and take them into consideration. And if they are important in their bearing on project operation they are very much more important with respect to future expenditure of national funds for reclamation.

National Duty—Stated in most general form, one Western sentiment is that it is the nation's simple duty to irrigate Western lands. Homestead lands in the Mississippi valley have a natural water supply, and Western lands should be turned over to the homesteader in equivalent condition. Suppose the hardfisted early irrigators did build their own ditch systems—that is no reason why under modern conditions the government should fail to recognize its duty to put water on the land for the farmer.

A slightly different view is that the Reclamation Fund does not belong to the United States but belongs to the West, and more specifically to the individual states, since it was raised by the sale of national lands situated in these states and wrongfully withheld by the nation from these states. One prominent citizen in particular argued this view to me vehemently and with a refreshing disregard of the customary amenities.

A third view, or rather an attitude (perhaps unconscious), of many reclamation farmers is that reclamation is not designed primarily to help the farmer or land owner, but is designed to help the United States as a whole. The entire business of reclamation, under this view, is essentially Uncle Sam's own private game, which he started for his personal purposes and which he is morally bound to see through. In less extreme cases, this view takes the form that Uncle Sam was not entirely selfish in the matter but that he does occupy the position of a sort of parent or guardian, and that, having also the biggest stake in the project, it is his plain duty to make the farmers prosperous and happy without regard to account-book questions. This has been called the Santa Claus idea of the government's part in reclamation.

Repudiation—Woven all through the fabric of thought on the projects is a widespread and definite element of repudiation sentiment. No one likes to admit it in terms; it is quite intangible; but it unmistakably colors the reclamation sky. One way of describing the senti-

ment is to say that those who hold it would be pleased if Congress passed a law or if some other thing happened to relieve them of the necessity of paying for the cost of the irrigation works. Another way is to say that the active repudiationist directs all his agitation and scheming and arguing toward proving that he never promised to pay, that he can't pay, that the engineers lied about the cost of the work and executed it incompetently, that costs have been negligently and fraudulently piled up, that waterlogging and the further expense for drainage resulted from the negligence of the engineers or even from the vengeful spirit of the director, that the Reclamation Service is responsible for exorbitant freight rates, and that the country at large has already put many times the alleged debt of the project farmers into its pocket in the shape of taxes and assessment rolls due to the growth of the project.

The ordinary man may find it hard to understand how the farmers, or any considerable number of them, can knowingly try to evade an obligation that they willingly assumed. But the matter of the obligation is not quite so simple. It would be simple if concerned with *homestead lands taken up after completion* of the works and announcement of their cost, which condition almost never occurs, however. Under the usual circumstances, the private owner or the early homesteader was not told what the works would cost, and such advance guesses as were made were often inadequate, so that in the end he found himself in for much more than he expected, a condition which everybody dislikes. Moreover, the law requires the farmer to pay the "estimated cost," and he thinks this refers to the advance guesses (often referred to as promises) rather than to the final estimates. He knows that the law does not create an inherent obligation anyway, but represents only a formal requirement on the part of Congress, which requirement has already been modified more than once by that body and which may be modified further if Congress is sufficiently urged. The contract that he may have signed was not really a free undertaking, but one that he, singly, could not well have kept out of. He believes also that the nation never intended to place upon him a burden greater than his ability to bear; and actual practice shows that his land, being located far from markets and being farmed inefficiently, does not produce enough to enable him to bear the burden conveniently on top of his other debts. So, believing that the government can better afford to lose the money than he can, he is inclined to welcome cancellation of his government debt, and he forms organizations to ask as a preliminary for forty-year extension or some equivalent postponement of payment. More correctly stated, his office-holding local representatives do this, not the farmer himself.

Another point bears on the same bit of psychology. Various people have circulated the idea that the whole reclamation business was a money-losing affair from the start and was known to be such. Perhaps some soft-headed government representatives have at times preached doctrines that helped build up this impression; but most of it is due to the efforts of out-and-out agitators. Such agitators say, for example, that interest payment was remitted in the original Reclamation Act because it was known that irrigation was an unprofitable adventure; that all the good projects were developed by private capital, and even most of these

are not able to pay interest on the construction money; and that the government, in return for its loss of interest, gains tremendous amounts of income in taxing the wealth which it creates. By such ingenious bits of reasoning, these people try to yoke together in the general Western consciousness (1) the belief that reclamation cannot pay interest and perhaps not more than a small fraction of the principal, because it is unprofitable; and (2) the conviction that the nation should hand out great additional sums for further construction, because reclamation is profitable. It is going to be difficult to graft these views upon the thought of the country generally, or to get wide support for the development policies which they suggest.

But this is only another case of how the agitators have hurt reclamation. The reclamation farmer's financial credit has already been impaired by agitators, as expressed very definitely by Land Bank officials, and now the same agitators are creating doubt of the wisdom of doing more reclamation. Some day the farmers are going to wake up to how ill they have been served by the agitators.

The Pork Barrel—Following another line of thought, many men in the arid states feel that it is time the government did something handsome for them, after having lavished federal funds on rivers and harbors to the benefit of Eastern communities for these many years. Doesn't Congress take large sums of money out of the public treasury to benefit New York and Philadelphia by building them harbors and dredging channels? Doesn't it subsidize the Ohio River cities by canalizing the river at tremendous cost, and the farmers of the Mississippi River bottoms by leveeing the banks? Well, then, with equal justice the Western states may ask for government expenditures for the public good! And this means Treasury money, not Reclamation Fund money, because that belongs to the West, not to the United States, having been raised from Western lands and duly consecrated to the West by Congress in the Reclamation Act.

It needs no special imagination to picture the development of reclamation if the spirit of this school of thought comes to prevail. The long odorous pork-barrel system when extended to irrigation and drainage would furnish new and interesting possibilities. Senate votes for power grants on the Colorado might be traded in legitimate legislative manner for cessation of a filibuster on a deficiency appropriation for the Columbia Basin work (assuming that project to have been started by then).

State Apportionment—Definite convictions are entertained in most parts of the West concerning claims of the several states to reclamation money. The provision of the Reclamation Act which requires money to be expended according to geography rather than efficiency is partly responsible, no doubt. But even aside from this there is enough local rivalry, or jealousy, to keep these convictions alive. Their importance lies in the fact that such matters as water supply, soil, topography and settlement make reclamation difficult enough, without the intermixture of ward politics. The general citizen presumably believes that, if national expenditure for irrigation should rest on the basic consideration of efficient use of the money, the most productive and profitable projects should be undertaken. The believer in state apportionment may grant the premise but he denies the conclusion.

Alum Shortens Drying Period of Imhoff Tank Sludge

Laboratory and Operating Tests Lead to Adoption of Alum at Joint Sewage-Works of Plainfield, N. J.

Paper No. 130 of the Journal Series, New Jersey Agricultural Experiment Stations and New Jersey State Department of Health, Substation, Sewage Investigations, by Willem Rudolfs, John R. Downes and F. Leslie Campbell, respectively, Chief, Sewage Investigations, New Brunswick, N. J.; Superintendent, Plainfield Joint Sewage-Works and Member Research Committee, New Jersey Sewage Works Association, Green Brook Park, Bound Brook, N. J.; and Research Chemist, Sewage Investigations.

LABORATORY experiments on the effect of certain chemicals upon the rate of suction filtration of ripe Imhoff sludge made by Van der Meulen and Smith showed that aluminum sulphate gave the best results and suggested the addition of alum to the sludge to increase the rate of gravity filtration and evaporation on sludge-drying beds. (See *Jour. Ind. Eng. Chem.*, XV, 281, 1923.) The experiments were carried out at the Plainfield, N. J., joint sewage-works. Some of the drying beds used were located about 60 yd. from the Imhoff tanks. The sludge flows from the tanks along a trough into a mixing pit and is then pumped out upon the beds.

Van der Meulen and Smith used 6.7 lb. of aluminum sulphate per cubic yard of sludge. We used from 2.7 to 3.5 lb. per cubic yard. For gravity filtration it is desirable to have a quickly formed porous mat of gas-permeated solids floating on clear liquid, and it is this condition that we strove to approach in our work.

Investigators have stated that rapid and uniform mixture of the colloidal material with the electrolyte is necessary to insure maximum flocculation. At first glance it seemed in our practical experience necessary to obtain a thorough mixture of the alum and sludge by stirring; accordingly, a motor-driven stirring apparatus was devised, consisting of the blades of a small boat propeller fastened to a long iron rod. This apparatus, put in operation at the Plainfield plant, showed at once that the stirring affected the appearance of the sludge materially. Upon examination it was found that the comparatively porous material—sludge aggregates interspersed by gas bubbles—became finely divided, leaving the finely dispersed material devoid of gas bubbles with a liquid film on top. It is desirable to have large flocs interspersed with fairly large gas bubbles in order that the liquid movement may be downward and thereby facilitate the draining off of the transparent liquid. The violent stirring of the propeller apparently beat out the CO₂ formed by the acid alum acting on the carbonates of the sludge, whereby the porosity of the solids was destroyed causing them to sink to the bottom. Further tests, in which the time of stirring ranged from one-half minute to ten minutes, were made but in no case were the results as satisfactory as those secured by gentle mixing in the following manner: The calculated amount of alum solution was siphoned into the sludge as it flowed slowly by in the sludge channel at a point where the stream of sludge turns at right angles to itself to pass through a shear gate to the bed. The right-angle turn folds the sludge over on itself, which motion, together with the drop into the bed, gives adequate mixing and the reaction is completed in quiescence so that the floc is not again broken up. Consequently the stirring apparatus was discarded in subsequent work. Tests were made in January, April and May of 1923 in the latter manner, and several treatments were made by the superintendent without checks to relieve the overload condition of his tanks.

The day after the January experiments were made a

heavy snowstorm accompanied by frost and resulting in a thick layer of snow, prevented us from making daily observations. The initial amount of sludge in the beds had shrunk considerably in the course of nine days. When the material was taken off the treated sludge consisted of a fluffy, spongy mass while the untreated sludge was stiff and hard.

The amount of moisture present in the samples taken from the April experiments does not give a fair representation of the consistency of the drying sludge. The first few per cents of moisture are rapidly drained off but as drying proceeds the release of water becomes increasingly difficult and the sludge remains gelatinous for several days. This is very apparent when the moisture contents are compared with the time when the treated sludge was ready for forking.

make a few trials at their own plants to determine the exact amount of alum necessary for rapid dewatering.

The alum used was bought in large quantities at \$1.75 per 100 lb, so the cost of treatment is well within practical limits. The total cost, for instance, is so small that variations over the range indicated in the chart would mean a variation between \$28 and \$51 a year for each m.g.d. of plant capacity.

In addition to the rapid drying, the sludge has a better texture for removal from the bed. Rain, even during the first few hours, has little effect on the drying as compared with untreated sludge.

There are no odors from the treated sludge. Local sludge gives some odor when untreated, during the first and second evenings after drawing. The treated sludge, when dry, is less voluminous than the untreated. The treated sludge

RATE OF DRYING OF IMHOFF TANK SLUDGE

No alum used in 1919, 1920 and 1922. Alum used in 1923, at rates stated. Long bars indicate time one dose of sludge remained on bed to dry, each square being a day. Results for each of five beds shown separately. Rainfall and temperature plotted because of their relation to drying period;

WITHOUT AND WITH ALUM ADDED TO SLUDGE

also, for each day, whether cloudy during daylight, rain or showers—a shower being a rainfall of less than 0.1 in. "Scum" indicates that bed in question was used to dry grease skimmed from tank instead of to dry sludge; results not comparable in such cases.

The May experiments were conducted with slightly different amounts of alum. Again the moisture content after ten days did not differ greatly but the appearance of the treated and untreated sludge was marked. Circumstances interfering with the securing of proper check experiments made it impracticable to carry on more controls. The superintendent, however, was so impressed with the advantages of this dewatering that he has applied the results of the experiments to the regular routine operation of the Plainfield sewage-works.

In the accompanying diagram the results obtained by drying alum-treated sludge during April, May and part of June, 1923, are compared with the results of drying untreated sludge during the same months of 1919, 1920 and 1922 (1921 is omitted because repairs to the concrete of the sludge channel in that year interfered with drying during this period). The treated sludge dried in approximately half the time required for untreated sludge. Alum to the amount of 3 lb. per cubic yard of sludge increased the acidity to pH 5.4 to 5.7, the original pH values being 7.4 to 7.6. Larger amounts of alum will give still shorter drying periods, but in view of the fact that with even the smallest amounts rapid drying is secured, we feel that no great advantage is gained by shortening the drying periods by one or two days at a much higher cost. It is apparent that the dose is not very critical within a wide range and operators could readily

cracks within five hours. As with untreated sludge, best drying results are obtained by keeping the original thickness on the bed down to 9 or 10 inches.

The improved results of treatment since May 22 are due to a more thorough appreciation of the fact that the agitation should be kept down to a minimum and the dose applied as close to the drying bed as possible.

Laboratory work at the sewage substation, which will be extended and reported separately, later has furnished some explanation of the favorable results obtained by minimum agitation and has indicated that this minimum is so low that it has apparently escaped the notice of other observers. A second optimum condition of flocculation can be obtained, but only with an unwarranted excess of energy and alum.

Progress in Development of Non-Corrosive Steels

Great strides in the development of non-corrosive steels may be expected during the next few years in the opinion of Dr. G. K. Burgess, director of the Bureau of Standards. The waste represented by the corrosion of steel is so great that its prevention by the development of these special steels constitutes, in his opinion, one of the most important present-day trends in the steel industry.

Federal Land Reclamation: A National Problem

6. Difficulties and Complaints of the Farmer

By H. H. BROOK

President, Elephant Butte Irrigation District, Las Cruces, N. M.

THE SUCCESS of the federal reclamation projects does not depend primarily upon perfect engineering, or upon rules of farming, or terms and regulations laid down in Washington. Success will depend upon the ability of the average settler to overcome the trials of creating wealth and making a home where nature never intended there should be one.

The building of a dam or a canal is a comparatively easy problem, rules for which can be found in scores of handbooks, but there is no formula for welding thousands of diverse human factors into a prosperous happy community.

Considering that the settler is the one who will pay the bills, his voice is relatively small and weak in the battle of words that is now taking place. Possibly there would be less complaint and more success if his advice and counsel were solicited. By training and habit he is not a speaker or a propagandist. He has, however, great powers of resistance. The great majority are united in the belief that they cannot meet payments twice what they expected when they signed their contracts, without disaster to at least three-fourths of the present settlers. Assuming that the doubled costs are perfectly legitimate and necessary, the settler should not be called upon to pay them in the same time he agreed to pay one-half as much. If it was not wrong for the Reclamation Service to have underestimated by one-half the work necessary, it is not wrong for the settler to ask for a longer time to pay this increased cost. The settlers as a whole do not want to avoid or repudiate payment.

Private and Federal Irrigation Contrasted—Business men and corporations weigh their possible earnings very cautiously before making large expenditures for fixed investments. Every promoter of private or corporate irrigation enterprises realizes every minute that the success of his project depends on the ability of the farmer to make enough money for the living of his family and the upbuilding of his farm. Consequently, every cent is expended *with a view to the ability of the farmer to pay*. The contrast of the reclamation project procedure is striking. Here the spending is done without any direct connection or relation between the earning capacity or the success of the enterprise as a whole. Well constructed engineering works do not insure success. The financial caution that animates every private enterprise is very remote.

While the Service contains a splendid body of loyal conscientious employees, and in most instances we are proud of their work, nevertheless it cannot be asserted that they are not fully conscious of this irresponsibility for the ultimate success of their work, and the mighty power of the government that protects them, and cloaks their mistakes. Generally speaking, they have no farm experience and no sympathetic understanding of the farmer's problems. Most of the criticism of their work

The Sixth of a Series of Articles on the History and Performance of the Great Government Adventure in Irrigation of the Arid Lands of the West.

comes from the farmers. Unless extreme precautions are taken a spirit of bitter enmity and disrespect for the farmers arises and influences their work. They are only human and the system of government work encourages these conditions.

A concrete example of the results of this lack of relation between the earning and the spending agencies is in the Rincon Valley of the Rio Grande project. The Rio Grande project cost has been announced as \$90 per acre for all lands. In the Rincon Valley over \$100 has already been spent, and \$35 more per acre must be spent before the lands can be farmed, making a total cost of \$135 per acre. This is \$45 more than each acre will pay—the deficit being assessed against all other lands of the project. Much of the land in this valley will never be worth \$135 per acre and it will be many, many years before any substantial part of the lands are worth that amount. It is a long narrow valley requiring many expensive river crossings and the works are menaced by arroyos in many places. There is no reason why the engineering difficulties and costs could not have been as well estimated ten years ago, before the work started, as today. With advance knowledge of these costs, the landowners certainly would never have approved the work on the present plan. Trusting in the government, they did not know what the cost would be until it was too late to stop.

Reclamation Service Secretive—This cause of ill feeling is further aggravated by a lack of frankness and free exchange of information between the Service and the farmer. Due perhaps to much unjust criticism in the past the Service has become pretty much of a close corporation. The system of accounting is not such as inspires any degree of confidence. Unnecessarily intricate and confusing, the farmer looks upon it as an instrument for his undoing. In general the farmer is only given such information as is considered good for him. Of course, any information specifically called for is always furnished but only so much and no more. Very often information is gathered at the farmer's expense for the specific purpose of refuting and bringing confusion upon him when he attempts to complain. Rightly or wrongly the farmer very soon reaches the conclusion that the power and resources of the department are leagued against him. There is not, as a general rule, that friendly feeling of co-operation, good will and sincere desire to help, that should rightly prevail between parties whose interests should be mutual, if not paternal.

These conditions—avoiding responsibility, lack of candor and secretiveness—which have caused so much trouble, have been relieved on the Rio Grande project in recent years by a policy of greater co-operation and mutual understanding between the project manager and the official representatives of the farmers. The project manager refers all major policies and construction fea-

tures to the farmer's representatives, who are allowed to discuss and pass upon them, thus dividing responsibility for the success or failure of this particular matter. In earlier days, and even yet on many projects, the farmers are allowed no voice in the manner and policy of the work after the contract is signed. Often the farmer's advice is found valuable, his experience prevents mistakes, and his backing changes to approval what would otherwise be resented and condemned. Long experience with project farmers proves that the majority are generally fair, reasonable and sound. If taken into confidence by a studied policy of consistent project publicity, telling them fully the whys, wherefores and costs of each thing, admitting the mistakes and calling attention to successes in a simple, clear, frank and open manner, they would be found on the right side in practically every instance. The theory that silence reduces the amount of trouble stirred up is a fallacy. The farmer is an extremely suspicious individual but a staunch friend when once his confidence is won.

Farmers Not Incompetent—From articles and discussions of various reclamation enthusiasts, concurred in to considerable extent by the bureau heads, the average person would gather the impression that the greatest part of the financial difficulties on reclamation projects was due to *incompetent* settlers. Not only is this fundamentally untrue but it is such a specious line of reasoning, so constantly reiterated, and so harmful to the splendid work of reclamation that something must be said about it from the farmer's viewpoint. Our reclamation theorist, with naïve ingenuousness, loudly proclaims that the reason his theory hasn't worked is, forsooth, because the settler isn't competent. Wonderfully convenient idea, and so simple and plausible! But have any facts been produced to prove it? None that we have ever seen in many years on the projects.

The accepted axiom that it has taken three failures to make one success on the reclamation projects does not *ipso facto* prove that the three failures were incompetents. It might as easily prove, what nearly all the actual settlers contend, that the building of a modern community out of the desert in defiance of nature, and the payment in twenty years of vast irrigation works beyond the scope of private capital, is a burden beyond the ability of the average good farmer to carry.

It is true that there are incompetents and drifters on all our projects, but in no greater proportion than in any other western occupation. Even the Reclamation Service has its incompetents, and probably in as great proportion. As a class, the men that go upon our western projects are not incompetent. They are of the same pioneer stock that has made our western country great—the class that in a few decades has built the country of which we are wont to boast.

It is urged that the settlers on federal reclamation projects be selected for their fitness. If the law of averages must be eliminated, is it not a confession that the terms are too severe? Are we to have an example of the "law of the survival of the fittest" administered by some bureaucrat instead of by nature?

Drainage Losses—A dilatory policy with regard to drainage has been the source of an inconceivable amount of financial difficulty on many of the projects. Losses from seepage were allowed to occur, often aggregating more than the total cost of the project. Many

farmers lost their holdings and the savings of a lifetime. All of them have been so crippled financially that it will take many years of fair returns to recover any large ability to pay. The excuse offered by the Reclamation Service is that the farmers would not vote to approve the cost of drainage. This is true, but, while on the face it seems a valid excuse, upon analysis it is found superficial and unsound.

It cannot be denied that the engineers of the Service were charged with all the responsibility of laying out and estimating the needs of a project and its cost. Theirs was the technical knowledge, and their recommendations were final. The impression was given that a fatherly government would call in its wisest men, devise the best system and the farmer need have no fear or suspicion. The farmer was allowed no voice in planning and, admitting his ignorance, relied upon the federal engineers' assurance of an adequate system and a properly estimated cost. Very soon it became apparent that the irrigation works were going to exceed the estimated cost. The farmer saw evidences of mistakes, experimentation, and what appeared to be lavishness, that shook his faith and confidence. Few of the farmers realized the danger of seepage, and before this danger was fully apparent he was asked to sign a new contract for a greatly increased cost to cover drainage. True to every natural and human instinct, and not realizing perhaps that he was trapped, he rebelled and refused to sign.

In the first place, there is no possible excuse for the government engineers not knowing the necessity for, and providing for, drainage in the original estimates. It was discussed but no allowance was made, because (it is weakly contended) it could not be determined whether it would be needed or not. On the Rio Grande project, at least, the noted English engineer, Sir William Willcox, warned the government of its error in unmistakable terms before the project was even begun. In the second place, having for one reason or another overlooked this obvious duty and responsibility, a more aggressive policy should have been pursued to remedy the pending tragedy. What was actually done was to sit back and say in effect, "Sign on our terms or drown, your sins are on your own heads." The Service has often exercised arbitrary power in less important matters and having, as they contended, a contract for the payment of the actual cost no matter what it might be, why couldn't they have arbitrarily insisted upon drainage?

Furthermore, realizing full well the pending tragedy, and if the signing of a new contract was an absolute necessity, what was there to prevent an intensive publicity and educational campaign early in the development? The government could well have afforded to spend thousands of dollars in such educational work. A few formal warnings were issued, but it remained for the farmers to organize such an educational campaign after the damage was done.

The Government Benefits—As to benefits: bearing in mind that no agricultural development is possible in the arid states without irrigation, and that such development is vital to public progress, which is recognized in the extraordinary powers granted to irrigation districts, is it not clear that the chief and primary beneficiaries of irrigation development are the nation, state, county and cities? These institutions are perpetual, the individual is transitory. The individual

hopes to make a profit, and occasionally does, but the nation, state, county and city inevitably profit in perpetuity both on the improvements and production. The nation's meat supply, the vast cattle and sheep breeding ranges, are protected from the scourge of periodic drouths. The cities and towns in most instances in the arid section are largely dependent for their prosperity upon the production of the irrigated lands.

The original plan of the Reclamation Act was to finance those projects which are beyond the scope of private interest-bearing capital. The avowed purpose was the establishment of contented rural homes, but this idea is first predicated upon national welfare in the recognized advantages of a home-owning agrarian population and the increase of taxable wealth.

Federal aid alone, as given by the reclamation law, does not accomplish this aim. It requires the extremely hazardous co-operation of some venturesome individual with an abundance of brains, money and energy. It is an axiom of the irrigated West that every success is built upon the cumulated efforts of three failures. To successfully create a prosperous farm from the desert, even with federal aid, is a vastly more hazardous job and requires a higher and more able type of citizen than it took to develop the free homestead lands of the Middle West.

Pioneering Unprofitable—The up-building of the country, as recited, is a necessary adjunct to profitable farming and must be done during or before the farmer can be expected to pay for irrigation works. In the meantime, he must house, feed, clothe and educate himself, his wife and children. Does it seem reasonable or feasible? Can anyone assert that the pioneer farmer has even an infinitesimal chance of profiting in proportion to the government? The farmer takes all the risk and experience shows that a very large majority of the pioneers lose. Except for gross mistakes, the government takes no risk and can't lose.

Since the benefits of increasing farm homes and national wealth are unquestionable, and the works are not private, but public, to be enjoyed by the nation for all time, what sound reason is there for not extending the time or repayment to a point where the purpose of contented homes and increasing national wealth can be accomplished without a trail of discontent, hardships, failure and tragedy?

The conclusion should not be drawn from this article that reclamation is a failure—far from it. The development of our natural resources through reclamation is the best and most profitable investment the government has made or can make. Every dollar invested has already returned manifold in national wealth. These facts need not be repeated.

The Reclamation Service has unquestionably been one of the best administered bureaus of the government with no taint of politics, graft or intentional wrong. Compared with the public management of our roads, schools, counties, municipalities and other corporate large scale irrigation systems, the Reclamation Service has done fully as well as, if not better than, the people would have done under their own management. In fact, it is vital in some instances to have an organization in charge that is not influenced in the least by local prejudices, habits or politics. This article attempts to give the farmer's close intimate views of some of the causes of the complaint and criticism arising on the projects

Protecting Highway Bridges From Colliding Vehicles

Destruction of Bridges by Collisions Becoming More Frequent—Skid Beams, High Curbs and Traffic Guides Advised

By E. F. KELLEY

Senior Highway Bridge Engineer, Bureau of Public Roads, Washington, D. C.

IN LESS than two years *Engineering News-Record* has published accounts of the destruction of four steel truss bridges by motor vehicles which collided with the truss members. The last three of these accidents occurred within eight months. Doubtless other accidents of a similar nature have occurred which have not been reported in the technical press, and the writer knows of one such case in which the end post of a truss was wrecked by a truck, although the complete failure of the structure did not ensue.

The situation is grave, as has been pointed out editorially, and it promises to become more serious as time goes on. With ever-increasing speed and density of traffic, such accidents will doubtless occur in ever-increasing number. Therefore the problem of the adequate protection of bridge structures, particularly steel trusses, from injury or total destruction by motor vehicles merits the careful consideration of every

engineer interested in the construction or maintenance of highway bridges. The problem is not a simple one, involving as it does not only development of suitable structural details but also the important item of additional expense.

From the reports of accidents it is evident that not only the end posts but also the entire web system must be afforded protection. End posts may be adequately protected from

DAMAGED HIP VERTICAL
Showing absence of adequate protection.

vehicles approaching the bridge by massive masonry posts, but protection of either end posts or web system from vehicles on the structure or leaving it is not so simple.

Skid Beams—In a letter published in *Engineering News-Record* of Jan. 18, 1923, p. 131, is found the suggestion that the trusses be protected by skid-beams such as are in use on railway bridges. Undoubtedly this would be a step in the right direction. Such members, if of sufficient strength and properly placed, would give much better insurance against accident than is now usually afforded. However, their appearance and cost might cause some objection to their use, and they would also involve some rather difficult details.

For the most effective protection, the beam supports should be independent of the truss members. Several lines would be necessary, for the truss must be protected not only from fenders and hubs but also from overhanging bodies, and this would necessitate that the

top beams be placed at some considerable distance above the bridge floor, which might mar the appearance of the structure. Also the beams would necessarily be of greater strength in proportion to the weight of the traffic units than in the case of railway bridges; for, on a highway bridge wide enough for two lines of traffic it is entirely possible that a vehicle may strike the rail almost head-on. The cost of providing steel rails that would stop a charging truck would seem to be prohibitive.

Protection by Curbs—The suggestion that the necessary protection be afforded by adequate curbs seems to offer the most satisfactory solution which has been advanced. But here again we are confronted with questions of appearance and cost, as well as with the fact that the necessary curb construction will scarcely be feasible on bridges not floored with concrete.

Curbs which will stop a car must be at least as high as the center of the wheels. This means a minimum

It is to be noted that by flaring the ends of such curbs and extending them out onto the approach fill or pavement at the end of the bridge, the end posts of the bridge may be protected from approaching vehicles.

Traffic Guides—In addition to the positive protection of the structure by mechanical means much may be accomplished by means of traffic guides, especially those which are effective at night. Marking traffic lanes by lines painted on the roadway surface has proven most effective on pavements, and it should be equally effective on bridges. Painting the handrails a light color, which is practiced in some localities, also adds to the insurance against collision.

Public Safety—Of equal or greater importance than the protection of the structure from injury or destruction is the protection of the traveling public. For a number of years the Iowa Highway Commission has kept a record of accidents of all kinds which occur on the highways of the state. The commission's *Service*

TWO TYPICAL BRIDGE ACCIDENTS DUE TO

At left: Wreck of bridge over Little Patuxent River near Savage, Md., two years ago; in spite of signs warning that the roadway was too narrow for two vehicles, a passenger car and a truck tried to cross at the same time, with the result that the web system of the trusses was knocked out.

MOTOR VEHICLES NOT HOLDING THE ROAD

At right: A recent accident near Alexandria, Va. The car was going at high speed, the approach to the bridge is a sharp curve, and the car failed to make the curve. As the structure is of deck type, the car merely went *overside*; a through truss bridge would have been wrecked.

curb height of 15 in. with 18, 20 and even 24 in. required for the larger vehicles; a curb 18 to 20 in. high will provide for the greater portion of traffic. From the standpoint of cost the curb width, or the distance from the face of curb to the clearance line of truss, is more important than is the curb height. The lack of standardization of truck bodies leads to a great variation in the amount of overhang, which may be as much as 30 in., possibly more in extreme cases. However, it is not practical, nor is it necessary, to provide for such extreme conditions. Based on information supplied by truck manufacturers, the conclusion is reached that a minimum distance of 12 in. from face of curb to clearance line of truss will be sufficient to provide for at least 95 per cent of motor vehicle traffic. This conclusion is given some added weight by the regulatory state laws governing widths of truck bodies, although too great dependence cannot be placed on legal requirements, as frequently they are not enforced and in any case they may be revised or repealed at any time.

Such curb heights as are suggested here may be a shock to our conventional ideas of appearance. Again, the extra curb width will add to the cost of the structure by requiring that the trusses be placed farther apart to give the same width of roadway between curbs.

Bulletin reports that 58 automobiles went through bridge railings in 1921, while 64 similar accidents occurred in 1922, with a total of 130 persons injured in the two years. This is the record for one state of the forty-eight. Does not the situation demand a remedy? On through truss bridges the protection which will safeguard the structure will also safeguard traffic. On other structures substantial curbs or railings are necessary.

In some states it is the practice to insure an adequate width of approach fill at the end of the bridge by building flaring abutment wing walls with horizontal tops for a portion of their length. On this horizontal portion is constructed a substantial rail of concrete or other material in keeping with the structure, and the fill is maintained at roadway level to the end of the rail. The wing rail and the added width of approach fill increase the safety of vehicles by affording actual protection from accident, while the rail increases the visibility of the bridge and gives it an improved and finished appearance.

The above discussion is presented to emphasize the facts and opinions which have already been published, in the hope of arousing engineers to the need for a most serious consideration of the situation, to the end that our bridge investment may be safeguarded.

Present-Day Street and Pavement Practice for Cities

A.S.M.I. Discussion Recommends Increase of Radius and Widening of Curves—
New Penetration Requirements

Abstract of Report of Committee on Street and Highway Design, presented at convention of the American Society of Municipal Improvements, November, 1923: E. R. Conant, chairman, P. L. Brockway, S. Q. Cannon, H. E. Barnes; together with papers on details of street and highway design.

Report of Committee on Street and Highway Design

THAT municipal and other engineers are recognizing the advantage of long radius corners is shown by the replies received to our questionnaire sent to many cities. Hartford, Conn., reports changing from 6 ft. to 12 and 15 ft. and states that a great improvement is noticeable with this change. Waterloo, Iowa, which formerly used 10 ft., changed a few years ago to 15 ft., and this year changed some dozen street intersections to 30 ft. Toronto, Canada, had originally 12 ft., then changed to 18 ft. and now has adopted 25 ft. Los Angeles reports that it uses a radius at curb returns equal to the width between the curb and property line, except where the distance on both streets is 15 ft. or more. In such cases the radius is made 5 ft. greater than this distance.

At Muskogee, Okla., the narrower streets are given the greater radii: 24- to 30-ft. streets have radii at corners of 12 to 15 ft., while for 30 ft. or over, a 10-ft. radius is used. Pawtucket, R. I., is increasing the radius from 15 to 25 ft. and Davenport, Iowa, 10 to 15 ft., Cheyenne, Wyo., new pavements are 18 ft. Other cities report adopting radii of from 10 to 225 ft.

Elimination of Catch Basins—There is a decided tendency towards eliminating catch basins and connecting the inlets direct to sewers or storm-water conduits and especially is this done where there are adequate-sized storm sewers with good slopes.

An unusual method of disposing of storm-water drainage is reported from Phoenix, Ariz. No storm-water sewers have been constructed. Walls of 6 ft. internal diameter are sunk to water bearing sand, usually 20 and sometimes 30 ft. below the surface. Brick is used for lining, laid open 6 ft. down from the top. With proper inlets into the wells, it is reported that satisfactory results are attained, the water-bearing sand taking away the discharge. Each well serves about 45,000 sq.ft.

Special Curb and Gutter Construction—An innovation in curb cross-section is being introduced which appears practical and beneficial. We all know that automobile and truck tires are often injured by grinding against the vertical rough stone curb. A few cities are adopting a curb with a batter on the gutter side and again this batter is sometimes merged with the gutter and the gutter and curb formed with a curved face. Jacksonville, Fla.; Shreveport, La.; Salt Lake City; Phoenix, Ariz.; Sacramento and Hartford are introducing this method to a greater or less extent. Quite a number of cities having bituminous pavements are introducing a gutter $4\frac{1}{2}$ to 6 ft. wide, built of concrete brick or hard surface, which will not be affected by gasoline or oil drippings from automobiles or trucks. Boise, Idaho; Muskogee, Okla.; Sacramento and St. Louis report this improvement.

Changes in Penetration Pavement Construction—The penetration limits for asphalt used in asphaltic pavements are being decidedly reduced, according to information received from a large number of cities. Also quite a few report using additional amount of dust. The changes bring about a harder mixture preventing pushing under traffic.

Information received from many engineers shows that they are increasing the concrete base thickness and, in some instances, increasing the thickness of the wearing surface. Peoria, Wichita, Davenport, Oak Park, St. Louis, Tulsa, Sioux City, Pontiac, Oklahoma City and New Orleans report increase of depth of base of about 1 in. The average adopted for heavy traffic is from 7 to 9 in.; medium, 8 to 7 in.; light, 5 to 6 inches.

Cost-Plus—George A. Carpenter, city engineer of Pawtucket, R. I., reports a rather unusual method of making payment, under the cost-plus basis. The paving done amounts to about \$300,000 per year and is contracted for and paid on the cost-plus basis. Before the contract is made, a fair estimate of the cost per square yard is agreed upon and the contractor is to be paid the actual cost, plus 15 per cent upon the estimated cost, if the final cost does not exceed this sum. If the final cost does exceed this sum, he is to pay all such excess cost, until his percentage of profit is reduced to 10 per cent, as figured upon the estimated cost per square yard. Beyond this point of reduction, the city will pay the extra cost. Should the contractor succeed in laying this pavement for less than the estimated cost, he will receive 15 per cent upon such estimated cost and one-half of the saving he will have made to the city.

Curve Widening

By G. A. CRAYTON
Springfield, Ill.

HIGHWAY curves, if sufficiently sharp, should be widened. There appears to be very little agreement in the practice of the several states in this country; which is shown graphically in Fig. 1. One state will widen a maximum of 8 ft. and others no more than 3 ft. The greatest

FIG. 1—HIGHWAY CURVE WIDENING PRACTICE

variation of opinion seems to be on curves of from 6 to 12 deg. It is the purpose of this paper to develop a method of widening that will be sufficiently flexible to meet all reasonable conditions.

It is a well-known fact that, when traversing a curve, the rear wheels of a vehicle will track inside of the leading wheels. Except in case of trailers built to track, each pair of wheels in a train will continue to track inside of those ahead of them. This, in the judgment of the writer, is the only logical reason for the practice of widening curves.

To develop a method for determining the necessary amount, it is first essential to determine the kind, general dimensions and construction of the motor truck and its trailers. As a rule, the longer trains will use "tracking" trailers. Our formula should, however, take account of the worst possible case, that of a motor truck of long wheel-base drawing a train of ordinary farm wagons. To make a few assumptions: (1) that there will be no side slip of the wheels; (2) that the path described by each pair of wheels

FIG. 2—CONDITIONS AFFECTING FORMULA FOR WIDENING CURVES

is an arc of a circle, after equilibrium has been established; (3) that the center of the curve will be the common center of all paths; (4) that the front axle of each trailer is at right angles to its tongue; (5) that each rear axle is at right angles to its reach. While all of these are not strictly true, it is believed that the approximation is sufficiently accurate. The conditions as outlined will result in the formula as shown in Fig. 2.

To secure some specific figures, assume a truck with a wheel-base of 144 in. and from one to five trailers, each being an ordinary farm wagon having a wheel-base of 7 ft. and a tongue length of 13 ft. Working out values on this basis, values of difference of track are obtained as shown in Fig. 3.

At last year's convention of this society, it was recommended by the Sub-Committee on Sidewalks and Street Design that in general the width of the roadway should be based upon a certain number of lanes of traffic and that a definite width should be allowed for each base. We will apply this principle to the case in hand, and assume that track difference constitutes the reason for widening. Highways of sufficient importance to warrant widening should be designed for a minimum of two traffic lanes. Each of these lanes should have applied the track difference as its extra width or a two-lane road should be widened double the tracking difference.

A better method of application is on a percentage basis.

FIG. 3—RECOMMENDED WIDENING FOR 18-FT. PAVEMENT COMPARED WITH PRACTICE SHOWN IN FIG. 1

The usual over-all width of a vehicle is 5½ ft., which requires in usual practice a 9-ft. traffic lane; then if a given set of conditions of a curve and vehicles cause a track difference of 1 ft., the "effective" width of the vehicle and train together is 6½ ft., and the width necessary for its traffic lane will be expressed by $(9 \times 6.5) \div 5.5$, in feet, or since two traffic lanes are under consideration, the total width of the curve would be $(2 \times 9 \times 6.5) \div 5.5$, or 21.27 ft., in which case the widening is 3.27 ft. This allows the same proportion of extra width in the strip between the vehicles as required by the vehicles themselves.

That we may compare the results by this method with current practice, Fig. 3 shows by curve the extra width required on the basis of a truck with two trailers on an 18-ft. pavement, the shaded area representing the "envelope" of practice shown in Fig. 1. It will be noted that in general the state requires more width than necessary on flat curves and less than required on the sharp ones. Or, expressed differently, the recommended curve is nearly a straight line, while nearly all of the practice curves are decidedly concave downward.

Some Details in Street Design

BY P. L. BROCKWAY
Wichita, Kan.

SOME engineers have thought that it should be possible to retain the very excellent qualities of the standard sheet asphalt wearing surface, and yet increase its resistance to internal flow, by adding larger, angular aggregate up to material passing a ¾-in. screen without any other modification of the mixture. A surface was constructed along these lines four years ago, on a brick surface which had been practically destroyed by the concentrated heavy traffic leading to two ice and cold storage plants, a large planing mill and a freight depot. Asphaltic cement having a penetration of about 45 was used. It had to be made specially for this contract at that time but it is now a standard product of the company from which it was purchased. There was used about half as much material over the ¾-in. and through the ¾-in. screen as would ordinarily be specified in the fine aggregate asphaltic concrete mixtures. Street temperatures ranging from about 0 to 125 deg. F. have been observed with standardized thermometers many times, the maximum being 137 deg.

Traffic counts indicate an average of 600 trucks daily or about 200 tons per foot width. In addition heavy reconstruction of some of the plants has caused some very heavy loads of machinery to pass over it and heavy, vibrating construction machinery to stand in one place for weeks at a time. The pavement marks up some in extreme hot weather but has not yet developed any waves or general unevenness of surface. The same mixture has since been used on several other of our heavier traffic business streets having traffic counts up to 10,000 vehicles per day and only one serious wave was developed. That where a 4-in. wearing surface had been laid to even up over the old pavement.

Another point in the construction of soft top pavement which is more pertinent than formerly is the degree of roughness of the base course on which the surface is laid. Many old pavements which were laid with rock aggregate so coarse that it was practically impossible to get an even contour, to say nothing of a smooth surface, are holding their own pretty well even under the punishment of greatly increased traffic. Other base laid with greater care in later years, and especially base laid without coarse aggregate having fairly smooth surface texture, has not fared so well. Examination shows that spots which give the greatest trouble from shoving of the wearing surface are above unusually smooth places on the concrete base. There was, therefore, developed a plan of artificially roughening the surface by marking across the base at intervals of about 18 in. by striking it with an inch rope when the concrete is still soft enough to be readily cut by the rough rope. The marks are made about ½-in. deep. This method has not been in use long enough to prove its merit but there is no ques-

tion that roughening of some kind will be an advantage.

A very troublesome kind of traffic to handle in cities in the agricultural territory is tractors loaded up to 15 tons and having deep lugs or cleats on the driving wheels. Concrete, brick and standard asphalt surfaces all fail alike under such abuse. Many places cannot afford granite blocks. Most cities, of course, try to concentrate this traffic on one or two streets.

It had been surfaced with penetration macadam some years earlier and, while it was not worn through, the surface was very badly pitted. The remaining patches of the surface were loosened and spread over the well compacted sand fill macadam. The new wearing surface was what might be called a plant mixed macadam. It was composed of limestone from 1 in. down, with all the dust and screenings retained. Screen analysis showed that it contained from 5 to 8 per cent of 200-mesh clean limestone dust. The specifications required that sufficient asphaltic cement having a penetration of 90 to 100 be added to thoroughly coat all particles and then about 0.5 per cent more be used and that it be mixed hot in a standard pug mixer. About 6½ per cent asphalt concrete was used rolled hot to a thickness of about 2 in. The texture of the rolled surface was quite porous because of the excess of large aggregate. On this was placed a squeegee coat of the same hot mix, running about 4 lb. per square yard. Hot, coarse sand was immediately spread over the whole surface and thoroughly rolled.

The objective was to obtain a mixture with an excess of plastic asphalt concrete which would rebond the surface material as often as it was displaced by the chopping action of tractor lugs. Over 20 lb. per yard was used. This surface has now been in use two years and, while there was some dissatisfaction the first year because some of the material would occasionally stick to an especially heavy wheel, it has proven so satisfactory the second season and is holding its contour and surface so well, that the tractor operators recently held an indignation meeting because the same material was not used on a main thoroughfare which they must occasionally use.

Another detail in pavement design which has proven very successful is the use of creosoted wood of 2-in. commercial thickness set with the grain vertical in transverse contraction or expansion joints in concrete pavement. Such joints have been in use twelve years without a single failure without costing anything for maintenance and without the objectionable lump which so often develops.

Modern Construction of Brick Pavements

By WILL P. BLAIR

Vice-President, National Paving Brick Manufacturers' Association, Cleveland, Ohio

THE MANUFACTURERS of vitrified brick, through the Western Paving Brick Manufacturers' Association, now advocate an asphalt in place of the portland cement filler for joints previously urged. This filler is a certain refined asphalt, which has the quality of maintaining its place in the brick joints, under extreme high temperature and does not become rigid and fragile under the influences of low temperature. The new filler affords such flexibility that the forces operating with an upward thrust against the brick surface [due to expansion of subgrade due to saturation or other causes] have little injurious effect. This filler protects the edges of the brick equally as well as the cement filler.

Important details subject to neglect and oversight are: (1) The stabilization of the subgrade by reducing to a minimum the possible moisture content, (2) the smoothness of the artificial base, (3) the uniform compression of the sand bed upon which the brick are placed. Unless compressed, the brick wearing surface will ultimately conform to any unevenness of the base surface. This requirement can only be accomplished by using a hand roller and filling the depressions noticed after each rolling. Three to four repetitions are necessary to accomplish the desired result.

Forecast of Railroad Situation in 1933

IN ORDER to check its estimates of the probable traffic increase in the next ten years and also to establish a practical basis for estimating the increase in railway facilities and the additional investment in railroads that would be needed in order to handle the increased business, the U. S. Chamber of Commerce Committee on Governmental Relations to Railroad Transportation sent a questionnaire to each of the Class 1 railroads asking them to check its estimates of the increase in traffic, and to state what physical facilities they would require to handle this new business. Sixty-two railway companies operating 166,810 miles of line, or 64.6 per cent of the total mileage in the United States, sent in replies which agree substantially with the committee's estimate that there will be an increase in passenger traffic of about 25 per cent and that there will be an increase of 33½ per cent in the ton-miles of freight. The results of these computations indicate that the railways of the country as a whole, in order to handle the increased traffic, will need to make the following increases in their physical facilities within the next ten years:

	Miles
First main track	5,350
Other main track	11,400
Yard and sidetracks	21,900
Total, all tracks	38,350
Locomotives	13,200
Freight cars	725,000
Passenger cars	12,300

Using present prices as a basis for estimating the cost of this new work and additional equipment, the capital requirements will be as follows:

Additions	\$5,339,874,000
Improvements	2,533,103,000
	\$7,872,977,000

This figure takes no account of the capital required for grade crossing elimination, automatic train control, and other safety provisions which will be, or already are, mandatory.

Westinghouse Brake for European Railways

The adoption of the Westinghouse brake by the railways of continental Europe has been recommended by the International Railway Commission (see *Engineering News-Record*, May 17, 1923, p. 871) and also by a commission which met recently at Paris as representative of the allied powers. The treaty of Versailles provided that Germany should equip its railway rolling stock with appliances facilitating the interchange of cars with the railways of the allied countries and these powers were to select a type of uniform continuous brake within ten years. The only other compressed-air brake considered was the Bozic which is used to some extent in Serbia. Choice of the Westinghouse does not involve its exclusive adoption, since any other system of compressed-air brake that can be coupled with and operated with the Westinghouse will be admitted in international traffic. Financial conditions may delay rapid introduction of the uniform brake, especially as Germany has made extensive use of the Kunze-Knorr brake since the war. The Paris correspondent of the *Railway Gazette*, London, ends a dispatch on the recent decision as follows: "In France we are not likely to see freight trains equipped with the continuous brake for many years, apart from those which were handed over by the American army and which have been the best advertisement of the Westinghouse brake that could have been desired."

South and West Unite to Promote Extension of Reclamation

Forestry, Reclamation and Home-Making Conference at New Orleans Discusses Reclamation Problems of the South

Engineering News-Record Staff Report

TWO HUNDRED men, largely from the South and Southwest, but with a goodly number from Utah, Idaho, Arizona, and California, met at New Orleans, Nov. 19-22 in answer to a call made by C. S. Ucker of Savannah, Ga., A. G. T. Moore and Walter Parker of New Orleans, F. H. Newell of Washington and others, to attend a Forestry, Reclamation and Home-Making Conference, under the auspices of the Southern Pine Association, the Florida and Mississippi Development Board and the New Orleans Association of Commerce.

Perhaps the most notable feature of the meeting was the spirit of co-operation shown between the South and the West, as evidenced by the remarks on the convention floor, corridor talks and a telegraphic exchange of resolutions between the Western Reclamation Association and the conference, all bearing on extension of reclamation to include cut-over, swamp and overflowed lands, chiefly in the South. Land colonization, the problems of the settlers, the revision of the present Reclamation Act and a variety of other topics were considered. A number of resolutions on future reclamation policy were adopted.

Permanent Organization—The conference appointed an executive committee with power to formulate a plan for permanent organization. Among its members are: Chairman, Clement S. Ucker, president, Southern Settlement and Development Organization; F. H. Newell, consulting engineer, U. S. Reclamation Service; and U. S. Senator William B. Bankhead of Alabama. It was voted to request the delegates to hold conferences in each state, Virginia to Texas. It was announced that the committee would take steps to form a Southern Reclamation Association and that the permanent organization would act as a clearing house for the association just named and others as well.

Co-operation Between West and South—All through the conference, stress was laid on co-operation between the West and South in furthering reclamation. Repeatedly it was asserted that the Reclamation Act of 1902 owed its passage to Southern votes, under the leadership of Senator Underwood and Congressman (now Senator) Bankhead of Alabama. This was attested to by men at the conference from both West and South, who said that it was the understanding, in 1902, that when the South called for federal aid in reclaiming swamp and cut-over lands the West would respond. Mr. Ucker of Savannah added that all the southern States, except the two Carolinas, Virginia and Georgia, had had public land and that such still exists in Florida, Alabama and Louisiana, where federal land offices are maintained. As representing the viewpoint of a westerner, it may be noted that in an interview during the conference, Congressman Addison T. Smith, of Idaho, chairman of the House committee on Irrigation and author of the Smith-Fletcher and the Smith-McNary bills, stated that there is no reason why the South cannot benefit in the same way as the West through federal aid, "to be repaid of course, by

the communities assisted." The swamp and marsh lands of the South he added, will be highly productive when placed under cultivation, and the South is entitled to assistance in solving this big problem.

Interest on Reclamation—The italicized quotation reflects on the desire in some Western quarters to get rid of the obligation to pay for the cost of irrigation works incurred by settlers when they took up land on the reclamation projects. The revolving fund which was to be formed by these payments has "stopped revolving," as Mr. Ucker said. Significant, also, in view of the absence of interest charges against Reclamation Service settlers was Senator Bankhead's statement that in the future no federal aid to reclamation ought to be given without interest charges to the beneficiary equal to what the government itself has to pay. George H. Maxwell and others also urged payment of interest on future reclamation loans.

Claims of the South—Speaking of the Western promises of 1902 to aid the South when called on, Col. Joseph Hyde Pratt, of North Carolina, said that only within the past two years has the South begun to be interested in reclamation, and that now this term needs a broader definition than that which has been understood in connection with the 1902 Reclamation Act. But aside from former promises, present-day conditions were urged in support of the southern claims. Thus, Senator Bankhead said that there are today ten acres of reclaimable land in South to one in the West, and that nowhere but in the South is there land available to meet the agricultural needs of the population a few decades hence.

Nation-Wide Policy Needed—A nation-wide reclamation policy, formulated by a well-rounded commission, was advocated by Col. Joseph Hyde Pratt of the North Carolina Geological and Economic Survey, Chapel Hill, N. C. Land classification according to adaptability for various purposes is needed. Lands subject to overflow that have been reclaimed are generally in use, due to their being located in settled communities. The case with swamp lands is different; it will take years to get them under cultivation. Of the idle worn-out lands, some should be planted to trees and some restored to cultivation. The cost of Western reclamation by irrigation has increased from \$30 to \$100 per acre. No \$100 projects should be put through. It is no longer true, said Mr. Pratt, that the West affords cheap lands. That promise has shifted to the South. Two great aids to reclamation would be topographic maps and improved highways.

Co-ordination in Water Control—A plea for co-ordination of many efforts having to do with utilization of water and protection of land from the evil effects of water when uncontrolled was made by Walter Parker, secretary of the New Orleans Association of Commerce. This co-operation should include federal, state, county, city, and rural agencies, and particularly the many federal departments and bureaus that work as if unaware of the others having to do with water. The late Senator Newlands, who took great interest in the matter, said Mr. Parker, was nearly defeated at the time of his last election to office because it was urged against him that his interests were too broad and that he should devote himself to the needs of Nevada. In 1917, Senator Newlands secured the passage of his Waterways Commission Bill. In 1919, he having died

meanwhile, the bill was repealed. The bill was again introduced last year and will be re-introduced in the next congress. The Waterways Commission Act, provided for the sort of federal study that must precede the formation and execution of a broad policy of water utilization and control.

Home-Making and Citizen Development—Throughout the conference it was repeatedly urged that home-making opportunities for persons of moderate means should be provided.

Improved Reclamation Methods—George H. Maxwell, of California, long well known for his advocacy of western irrigation, addressed the conference on Western Methods as Applied to the Southern Conditions. He laid down five principles of future reclamation development; (1) Reclamation must accord with a national policy; (2) Federal loans must be repaid; (3) Interest must be paid on loans; (4) the federal government must not serve as collector of principal and interest; (5) reclamation projects must be set in motion by the formation of districts having the power to levy taxes, issue bonds and make contracts.

Cut-over Lands—The vast areas of cut-over lands in this country, said John H. Kirby, president, Southern Pine Association, must be reforested if at all by public funds. Timber is the best all-round crop for the cut-over lands, in the opinion of E. A. Sherman, of the U. S. Forest Service. Col. Joseph H. Pratt, Chapel Hill, N. C., was not quite so sweeping as Mr. Sherman, perhaps because he had North Carolina conditions more particularly in mind, but he did say that for at least two or three generations a large majority of the cut-over lands should be reforested.

The Everglades and Other Florida Reclamation—Jules M. Burguières outlined the Florida Everglades problem, prefacing his remarks with the statement that these lands did not pass from federal to state ownership until 1903. The state now has title to about 1,800,000 acres of the Everglades, through which some of the needed drainage canals have been cut. In addition, there is an equal area needing drainage. The cut-over lands of Florida are increasing at the rate of 400,000 acres a year. The federal government should look into the economic need for reclamation in Florida and elsewhere.

Wet and Swamp Lands—Perhaps the easiest way to bring more land under cultivation, said S. H. McCrory, chief of the division of Agricultural engineering, U. S. Bureau of Public Roads, is the reclamation of wet and swamp lands. Of these there are in the United States about 100,000,000 acres, a large part of which require both reclamation and colonization.

Resolutions on Reclamation Policy—Of the resolutions adopted by the conference, the following two are of special interest as defining views on reclamation policy:

That we request Congress to consider the recasting of the entire reclamation law, making it applicable to all parts of the United States, eliminating the conditions which make speculation easy and which have encouraged tenantry and promoted soil deterioration, and at the same time extending the good features of the law so as to be applicable to the reclamation and best use of lands in whatever part of the country they may exist, such development to take place in time and manner best to promote the creation of opportunities for self-supporting and self-owned farm homes; also that the organization of a Reclamation Service be provided for by law and be placed on a permanent basis.

That full publicity and discussion be had of better methods of land settlement and provision be made under state laws for the organization of suitable semi-public bodies for taking option on desirable farm lands, appraising these, providing for favorable and easy prices and terms, preferably under some form of amortization, and that the condition of sale require actual settlement and cultivation under a system of agriculture found to be adapted to the locality.

Street Retaining Wall Founded on Fill of Large Boulders

Construction of Hillside Street in New York City Complicated by Riprap Fill at Site of Retaining Wall

BY HARRY W. LEVY

Engineer in Charge, Division of Design, Department of Public Works, Borough of Manhattan, New York City

NORTH of Washington Bridge, which crosses the Harlem River in the northern part of New York City, the easterly slope of Manhattan Island originally descended precipitously toward the river. Amsterdam Ave., a few hundred feet west of the top of the slope, and part of the side streets east of it are well built up. In order that property lying 200 ft. east of Amsterdam Ave. might be provided with better street facilities, Laurel Hill Terrace, a new north-and-south street, was laid out, interposing a street between this property and the public park lands lying to the east along the Harlem

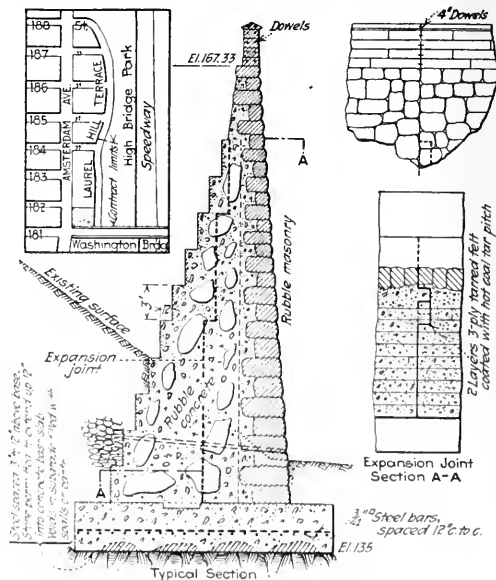

FIG. 1—LOCATION AND SECTION OF WALL
Greatest height of wall, 32 ft. 4 in.

River speedway. Existing street grades made it necessary to fix its elevation considerably above the original surface, and thus required the construction of a high retaining wall.

Before the grading of the street was taken up, large quantities of heavy rock fill and ashes had been dumped on the street site, filling the west part of it practically to grade, and sloping off into the park lands. To re-

move this mass of loose rock fill to the original surface, in order to construct retaining walls, would have necessitated excavations 50 ft. in depth through heavy rip-rap material of a sliding nature which could not readily be supported by sheeting on account of the steep slope

in the subsoil with stone or earth to hold the wet concrete mix; the specifications allowed large stones to project 12 in. above the bottom of the mat. The effective depth of the mat is 28 in. and the reinforcing consists of $\frac{3}{4}$ -in. square bars 12 in. on center both ways.

FIGS. 2 TO 5—LAUREL HILL TERRACE RETAINING WALL. A CONCRETE WALL BUILT ON OLD ROCK FILL
Upper left—Original condition of hillside, men standing on line of wall. Lower left—Rubble-faced wall on spread footing built directly on rock fill. Upper right—Finished wall seen looking southward from park at 18th St. Lower right—Ornamental stair tower and park approach built at 18th St.

of adjacent lands. The rock fill extended to a considerable depth, and consisted mainly of large, rugged pieces of stone, several cubic yards in volume, such as are taken out in cellar excavations in gneiss. Exploration showed that large open voids existed throughout the mass, but the fill as a whole was stable, observation and levels indicating that there had been no appreciable settlement over a period of years. In view of this, it was concluded that by spreading the load over a considerable area of this fill by means of a reinforced-concrete mat foundation the retaining wall could be constructed thereon without any danger of settlement.

The retaining wall varies in height from 10 to 30 feet. Its foundation was so designed that in case of settlement the mat would support the wall over any void up to 20 ft. span. It was placed after filling voids

No expansion joints are provided in the mat but the wall above has expansion joints of two layers of three-ply tarred felt every 40 ft. The retaining wall is of rubble concrete faced with rubble. The parapet wall and coping consist of a portion of the old Central Park wall which formerly was in front of the Metropolitan Museum of Art, seated on a new granite wall cap.

Provision has been made for regrading the fill within the park area so that in future a park path may be constructed and the intervening slope between this path and the wall graded and sodded without exposing the retaining-wall footings. An ornamental double stairway approach to the park, of rubble stone and cut granite, is constructed at the northerly end of the wall.

The work was constructed by S. Rosoff and Clemente Contracting Co. at an estimated cost of \$85,717.25.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

State Engineer on Apishapa Dam Failure

Sir—The Apishapa dam failure, described and discussed in *Engineering News-Record*, Aug. 30, p. 357, Sept. 6, p. 373 and Sept. 13, p. 447, which involved the total loss of the earth embankment primarily constituting the dam, again directs the attention of engineers to certain vital questions incident to the employment and maintenance of such structures which call for the most careful deliberation. Since the reports and comments thus far printed are more or less conflicting and indicate a somewhat confused impression of the situation, and since the writer has occupied the position of state engineer of Colorado and, consequently, ex-officio, that of consulting engineer for the structure, during its entire construction and operation period, being properly chargeable with responsibility for the plans and specifications adopted, and is, moreover, thoroughly familiar with the history, construction and operation, including repairs, of the dam, all such data being filed in his office, he feels that it is incumbent upon him to furnish to the engineering profession all essential information, to the end that correct conclusions regarding the causes of the failure may be arrived at and similar catastrophes be averted hereafter, so far as this is humanly possible. With this end in view it seems desirable to review, as concisely as possible, the more pertinent facts already published, adding such further detailed information in his possession as appears to be essential for a clear understanding of the problems involved.

Unfortunately, but perhaps unavoidably, the real issues have been considerably befogged heretofore by the publication of much that is extraneous to the vital questions, both in the reports that have appeared and in the comments thereon, and it seems best to eliminate from this discussion those features that have no direct bearing upon the failure of the dam.

It is conceded by all who have personally studied the situation and reported thereon that neither the matters referred to in the "protest and warning printed on the official record plans," mentioned in *Engineering News-Record*, Aug. 30, 1923, p. 357, and again, editorially, Sept. 6, 1923, p. 373, nor any of the appurtenances of the dam, such as riprap, cutoff walls, piling, spillway, freeboard, outlet tunnel, gates, drains, toes, etc., already sufficiently described in the earlier articles can be properly charged with any responsibility for the disaster; but the opinion that weaknesses of some kind or kinds existed in the earth embankment as constructed, and that these were primarily responsible for its failure, appears to be unanimously held. Therefore the writer will not discuss, at this time, any of these features not contributing to the failure, but will confine himself to those details which, in his opinion, bear some important relationship to what has happened. These details are as follows:

Nature of Dam—The dam was fundamentally an earth embankment having incorporated in it such appurtenances as were deemed necessary for the impounding and regulation of flood water for irrigation use, none of the appurtenances, however, being suspected of having contributed to the failure.

Construction—The embankment was constructed, so far as methods were concerned, in accordance with what were considered to be standard plans generally adopted among hydraulic engineers. The facts that three separate sets of specifications, all quite similar with respect to methods of construction, contemplating three distinct dams proposed for the site, each not to exceed 115 ft. in height, were pre-

pared at different times by different engineers or firms of engineers; that these three sets of plans were separately approved by three different state engineers; and, further, that the first specifications regarding the points now at issue are said by one of the members of the firm that prepared them to have been in substantial conformity with the then more or less standardized specifications of the U. S. Reclamation Service, are worthy of note. It is true that the different sets varied somewhat in their requirements concerning the amounts of water to be used in moistening the earth and in some other minor particulars, but they were all practically identical in leaving to the engineer in charge the final decisions as to the requirements for spreading, sprinkling and rolling. The embankment was considered practically completed by Sept. 20, 1920.

Material—Two distinct varieties of earth, described in considerable detail in the earlier articles and to be referred to again later herein, were used in the construction of the embankment. The suitability of the earth is questioned, especially by J. E. Field. (Sept. 13, 1923, pp. 418 and 420.)

Storage of Water—The reservoir was filled gradually to gage height 65 ft. on Aug. 3, the surface being then lowered gradually until the gage height was 47.3 ft. on Dec. 28.

1922: The surface remained at approximately 46 ft. until about May 10. Little water was available for storage that year and the surface gradually lowered until about Dec. 15 when the reservoir was practically empty, remaining at that stage for some months thereafter.

1923: No water was stored until after June 1. Between that date and Aug. 2 the water rose gradually from 14 to 48 ft. on the gage. The significant gage heights from Aug. 2 till the failure of the dam on Aug. 22 were as follows:

Date	Hour	Gage, Ft.
August 2	47.6
August 12	60.0
August 14	71.0
August 17	2 a.m.	71.3
August 17	7 p.m.	74.1
August 18	5 p.m.	75.7
August 19	9 p.m.	74.3
August 21	8 p.m.	75.1
August 22	3 p.m.	82.9

The water reached a gage height of 65 ft. on Aug. 3, 1921, after which it was drawn off gradually until it stood at about the 46-ft. level at the end of the year, where it remained until about May 10, 1922, then lowered to practically nothing at the end of that year, the reservoir remaining nearly empty until after June 1, 1923. It again reached the 1921 high-water stage of 65 ft. about Aug. 13, a little more than two years after it first reached that point. After Aug. 13 the water rose rather rapidly until, while still, according to the engineer in charge, about 11 ft. below the crest of the dam, the embankment failed at 3:00 p.m., Aug. 22, 1923.

Settlement and Cracking—The following details are abstracted from two letters dated respectively Sept. 14 and 16, 1923, from the engineer personally in direct charge of the project, A. N. Dallimore:

Following the time of maximum storage in 1921 two cross-sectional cracks developed, these being at distances of from 80 to 90 ft. from both the east and the west end of the dam respectively, each crack running from the water surface to the top of the dam, and the west one extending down on the back slope. These cracks were over the shoulders of the rock cliffs at points where the fills were much less than they were nearer the center of the dam and where the settlement might naturally be expected to be much less toward the ends of the dam than toward the center.

Another crack, running lengthwise of the dam and a little above the high-water mark, appeared also at the same time. Mr. Dallimore says that this crack was "probably caused by the fact that there was more settlement where the water covered the slope than on the slope above," and also that he considered it logical to expect such settlement cracks and did not consider them serious. He did not try to seal them up for some time, until he was sure they were not opening up any more. He then pumped water and

washed earth into them until they appeared to be entirely sealed. He reported that the maximum settlement of the dam up to May 10, 1922, "was about 2.5 ft., and about 3.5 ft. vertically on the slope at the water surface."

As the water rose above the 60-ft. gage height in August, 1923, there was some tendency to settlement on the front (water) slope at the west end of the dam, following the old crack there, and two very fine cracks showed on that end of the dam. These were the only cracks that appeared until just as the dam failed, when the diagonal crack described in the earlier articles opened up. The water entered the dam about 100 ft. from the east end and broke through the lower side at a point about 150 ft. from the west end.

the principal owners of the project and himself a graduate engineer, is quoted as being both pertinent and just:

"Regarding the care of the Apishapa dam by Mr. Dallimore, engineer in charge, will say that ever since he assumed charge of the company's system he has been at the reservoir frequently, and I know from conversations held with him that he was constantly on the lookout for settlement cracks in the dyke and fully appreciated that any such cracks which might occur would be possible sources of danger to the dam and should be given careful attention. I have asked him to report fully to you regarding what settlement cracks had occurred prior to the one which suddenly appeared and which caused the failure of the dam within a few minutes of its first appearance. I know of my own knowl-

APISHAPA DAM FAILURE: WATER JUST BEGINNING TO TRICKLE THROUGH NEAR THE WEST END

The water entered the dam near the surface about 100 ft. from the east end and immediately began to trickle out near the west end. The dotted line shows that the water

traveled along that course until nearly 2,000 sec-ft. was running through before the dam began to slough off. This would indicate a heavy crack along that course.

Leakage—Mr. Dallimore makes these statements in his letter of Sept. 11:

"The quotation from *Engineering News-Record* of Aug. 30, as follows, 'Leaks attributed to settlement cracks had been observed a year ago. . . . These leaks were at each end of the dam and about 25 ft. below the crest,' is not correct, as at no time, until just as the dam failed, has there been any leak through the dam. Some seepage developed through the rock cliffs in July, 1921, and occurred again this year when the water got up in the reservoir. On the west cliff this seepage was very slight and through the east cliff was about 2 sec.-ft. This seepage came through seams in the rock and was at all times entirely clear, carrying no sediment. It was carried off in ditches and did not get into the earth fill. [There had been no water at any elevation like 25 ft. below the crest between August, 1921, and August, 1923—A. J. McC.]

"At no time had there been any seepage at the toe of the dam, except through the drainage pipe in the old channel bed. At the time of the failure there was not to exceed 1 sec.-ft. coming through this pipe.

"The tunnel has shown no signs of soft spots or of seams washing out, at least up to the last few weeks, during which time we have had some large heads discharging. Eighty feet of the tunnel is lined below the gate chamber and I doubt if it will ever be necessary to line any more."

Supervision of the Dam—The following extract from a letter dated Sept. 11, 1923, from H. H. Knowlton, one of

edge that three hours prior to the failure there were no cracks showing along the line where failure occurred and Mr. Dallimore and the caretaker both told me afterward that they had inspected the whole dam looking for cracks after I did and within a short time prior to the break and that nothing showed at that time.

"After considerable water was in storage this summer Mr. Dallimore greatly increased the time and attention given to the reservoir and was always there to personally superintend the work when the weather gave indications that a flood might occur; and during the ten days prior to the break, during which time the water was being held at a level about 10 ft. lower than the spillway, he was at the dam practically all the time, day and night, and several nights did not even have his clothes off to sleep as he made frequent inspections of the dam during the night. He did this even though nothing had occurred to cause any real uneasiness regarding the safety of the dam. There was about 2 sec.-ft. of water seeping through the rock around the east end of the dam and coming out of the hillside in the form of clear water springs which did not touch the lower slope of the dyke, being carried away by ditches on the side hill. From two personal inspections of the dam made within two weeks prior to the break I know that the lower slope of the dam was entirely dry and that not to exceed 1 sec.-ft. of clear water was coming out of the drain pipe at the bottom."

All the evidence in this case leads to the conclusion that

the vital trouble was in the embankment alone and that 5 ft. more added to the height of the dam, or changes in the construction of the toes, would not have averted the disaster. It appears to be certain, also, that there had been no leaks through the body of the dam prior to the time of the break that would have given warning of impending danger. Nor does there seem to have been any upward pressure of any importance under the dam as suggested by Mr. Godfrey. (*Engineering News-Record*, Sept. 13, 1923, p. 447.) Indeed, Mr. Godfrey's premises with respect to the Apishapa dam being incorrect, his conclusions in this particular case have no bearing on the questions at issue.

Conclusions—In the light of the evidence and studies now given to the case, several items attract particular attention. These are: (1) The character of the earth used in making the fill; (2) the efficiency of the compacting that it received through sprinkling and rolling; (3) the interval of more than two years that elapsed between the times when the water reached the 65-ft. level; (4) the apparently very considerable settlement that took place after the water reached that level in 1921, and the development of cracks that appeared at that time; (5) the apparently unhampered flow of water into the dam soon after it rose above the same level and its practically immediate discharge at a somewhat lower level on the lower side of the dam nearly at the opposite end, both inlet and outlet being nearly enough on line with the bluffs to arouse a strong suspicion that settlement cracks and, possibly, cleavage planes along those lines in combination with an internal longitudinal crack, were largely responsible for the failure.

Compacting—Reviewing the situation, it now appears to the writer that the earth of which the embankment was composed should have been thoroughly compacted by means of a pool of water along the center line of the embankment, or, at least, by the utilization of optimum amounts of water, determined by trial. It appears to him to be reasonably clear that there was internal settlement and cracking when the reservoir was first filled to the 65-ft. level, caves forming inside the dam, the upper 50 ft. of which had been just sufficiently solidified by sprinkling and rolling to hold together without external cracking, possibly somewhat in an arch form. It seems probable that the water did not stand long enough at the higher levels in 1921 to saturate the entire body of the dam below the 65-ft. level, so there may have been a slight cantilever action in the upper portion of the embankment. The company, believing that there would be no further settlement below that level after the cracks had apparently been sealed, proceeded to add more material to the surfaces to compensate for the settlement, not suspecting the serious condition inside the structure.

These conclusions are presented, not with a view to fixing the blame upon any one connected with the work, but solely for the purpose of determining the nature of the fault in construction that was responsible for the failure. The state engineer will be blamed by some on the ground that the supervision was inadequate or incompetent. It must be remembered, however, that there are over 900 earth dams in Colorado that are under the supervision of the state engineer; that a number are usually being constructed at the same time; and that superintendents or inspectors appointed by the state engineer cannot, legally, be paid more than \$5 per day—hardly laborers' wages. Consequently much must be left to the owners and their engineers in direct charge. The state engineer's office can devote no more money or time to such work than it is now giving. In this particular case it was believed that those in charge of construction were more than usually competent, as, indeed, they were. The fact is that in forty years' experience as an irrigation engineer, more than ten years of that time as state engineer of Colorado, the writer has never before known of a failure like this one. He sincerely hopes that this may furnish such an object lesson to the engineering profession that there will never be another failure like it.

This discussion would not be complete without a word regarding the gates. It has been suggested by some that they should have had a greater discharge capacity. The writer does not believe this to be true. It is granted, of course, that the embankment should have been so constructed that

there would have been no danger of failure short of actual overtopping by some totally unprecedented flood. Granting this, it is to be remembered that the spillway capacity is practically unlimited and that the reservoir was intended to be a stream-bed reservoir for the conservation of flood waters. The gates were sufficiently large to furnish water for all prior rights along the stream below the reservoir, with an unusually large margin of safety. Under the existing circumstances, and assuming the dam to be properly constructed, there would seem to be no good reason for any larger outlet capacity. In short, the responsibility for the failure must be charged to the faults, whatever they may have been, in the embankment alone.

A. J. MCCUNE,
State Engineer.

Denver, Colo., Oct. 1.

Politics Not an Element in Opposition to Dr. Work

Sir—The following statement attributed in your issue of October 18, in an article "Work's Friends Justify Davis' Removal," to friends of Dr. Work, has just come to the attention of William Dudley Foulke, the president of the National Civil Service Reform League:

"The activities of the National Civil Service Reform League smack of first aid for the Democratic party. All its representatives who have called on Dr. Work have admitted affiliation with that party."

In reply to this statement, Mr. Foulke, who, as you probably know, was a close friend of Colonel Roosevelt, and who served as a member of the United States Civil Service Commission during the Roosevelt administration, has asked me to send you this statement:

"This statement is false. I was one of these representatives and no such affiliation was admitted by me, nor did it exist. I called on Dr. Work with two other members of the League. He asked me the question, 'What are your politics?' I told him I was an Independent. He said, 'That means you are a Democrat.' I answered that it did not, that I had been strongly opposed to the administration of Woodrow Wilson, to which he rejoined, 'Oh, that was a mere personal objection.' In fact, I have never voted the Democratic ticket since the administration of Grover Cleveland, but always either the Republican or the Progressive ticket. Dr. Work must be in hard straits if he finds it necessary to defend himself by the statement of an affiliation which he well knew did not exist."

I hope you may find Mr. Foulke's statement worthy of use in your publication.

RICHARD BOECKEL,
Washington, D. C., Washington Representative,
Nov. 23, 1923. National Civil Service Reform League.

Stanton's Expedition Down The Colorado

Sir—I note in your issue of Nov. 15, 1923, p. 787, under the heading "Engineering Plus Adventure" it is stated, "When it is remembered that the trip itself, devoid of any of the surveying accessories, has been made only two or three times and, with the exception of the pioneer Powell trip, only as an *adventure*, the Birdseye expedition becomes a notable addition to the annals of engineering."

The writer is evidently unaware of the notable expedition under the direction of the late Robert B. Stanton, M.Am.Soc.C.E., who made a most thorough and exhaustive survey and examination of the Colorado River and its canyons in the years 1889 and 1890, for the purpose of locating a low-grade railroad line to the Pacific Coast.

See *Transactions*, Am.Soc.C.E., Vol. 26, p. 283, also *Engineering News*, Oct. 18 and 25, 1890.

F. S. ODELL,
Port Chester, N. Y., Civil Engineer.
Nov. 20, 1923.

[The writing of Powell instead of Stanton in the editorial noted was a slip of the pen. Major Powell's famous exploratory trip down the canyon in 1869 was in no way a survey, but Mr. Stanton made a most thorough survey in 1889-90 for a possible railway. In the numbers of *Engineering News* referred to there are some excellent views of places in the canyon which have since become quite noted in engineering discussions.—EDITOR.]

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

Construction of a Concrete Power house and earth dam to develop a head of 62 ft. on the Manistee River near Cadillac, Mich., is contemplated by the Consumers Power Co. of Jackson, Mich.

Oregon City, Ore., Has Adopted the city manager plan and the city will elect a mayor and a treasurer Jan. 1, 1924. The mayor will appoint a city manager, who will name other city employees.

One of the Longest Ferro-Concrete bridges in England has been opened at Reading. The bridge crosses the Thames at a point which connects Reading with lower Caversham on the Oxfordshire side of the river.

To Keep Connecticut River Flood water back from the sewers in streets, covering an area of 328 acres, the Springfield, Mass., city council on Nov. 12 voted to appropriate \$79,000 for a pumping system and accompanying equipment. The system adopted was recommended by Metcalf & Eddy, engineers, Boston, Mass.

Several Weeks Probably Must Elapse before it will be possible for the State Department to call the proposed conference on oil pollution. The assembling of necessary data and reports is not yet complete. It is believed, however, that the situation has resolved itself largely into a matter of prescribing the mechanical devices necessary to make proper oil disposal comparatively easy.

An Important Civic Project at Dallas, Tex., is the extension and widening of Field St. from Main St. to Orange St. and Cedar Springs Ave., in order to provide a new cross-town route in the shipping and banking district. At present there is no continuous opening along this route and much of the property is occupied by barns and sheds which would be replaced by modern business buildings. This improvement was recommended by the late George E. Kessler, landscape architect, and it is now being urged upon the city by the Dallas Property Owners Association, of which E. N. Noyes is engineer.

In the Case of George W. Clark against the Green Briar Drainage District of Jasper and Crawford County, Ill. Mr. Clark has been awarded \$25,000 damages by a jury in the U. S. District Court at East St. Louis, Ill. He constructed a levee for the district several years ago and the district claimed that the levee was unsatisfactory and declined to pay the full amount due under the contract. Two years ago Mr. Clark obtained a judgment for \$30,000 but the Federal Court of Appeals remanded the case for a new trial. Counsel for the levee district has now filed a motion for retrial.

Chicago Rapid Transit Extension

A 5½-mile surface line extension of the Chicago elevated railway system is to be built in Evanston and Niles Center, under the name of the Chicago, North Shore & Northern Ry. From the present Howard St. station on the elevated system the new line will descend on an incline and run west to Niles Center, where it will turn north to a terminal at Dempster St. A site of about 55 acres has been secured for car shops for the elevated lines and the interurban line of the Chicago, North Shore & Milwaukee Electric Ry. An extension to Waukegan is projected, giving the latter railway an alternative route for its limited trains between Milwaukee and Chicago. Application has been made to the Illinois Commerce Commission for the necessary authority. The work will be under the direction of B. J. Fallon, general manager of the Chicago Elevated Railways.

Power Commission Grants More Licenses

A license to develop 29,000 hp. on Cascade Creek, 22 miles from Petersburg in Alaska, has been granted to Hutton, McNear & Dougherty of New York City and San Francisco. The license is conditioned upon a contract with the U. S. Forest Service for the purchase of timber as the power is to be used for the manufacture of pulp and paper. The project will consist of a dam, reservoir, a conduit 14,250 ft. long, and a power house and pulp mill. A preliminary permit has been granted to the West Virginia Power Co., of Charleston, covering a project on New River, five miles above Hinton, W. Va. The erection of a dam 140 ft. high and 750 ft. long is contemplated.

Another preliminary permit has been granted to Mary I. Crocker and J. W. Preston, Jr., of San Francisco, Calif., for a power project on the Mokelumne River and Sutter Creek within the Stanislaus National Forest, consisting of three reservoirs and three water conduits. The first conduit is approximately 22 miles in length with a capacity of 400 sec.-ft., the second approximately 7 miles in length with a capacity of 750 sec.-ft., and the third approximately 9 miles in length with a capacity of 350 sec.-ft. Three power houses will be built, the first to utilize a head of approximately 1,175 ft., the second 632 ft., and the third, 565 ft. The estimated total ultimate installation for the three is 48,000 hp.

To facilitate the handling of minor power projects the Federal Power Commission has authorized its executive secretary to issue licenses for ten years covering projects with a capacity of less than 100 hp., and field offices to issue licenses for ten-year periods covering projects of 40 hp. or less. If there is a possibility of the smaller projects conflicting in any way with larger projects the license is to be limited for five years.

Highway Officials Puzzled by Federal Reorganization Plan

Washington Correspondence

State highway officials apparently are in a quandary, judging from letters being received in Washington, as to the attitude they will take toward the proposal to transfer the Bureau of Public Roads from the Department of Agriculture to the Department of the Interior. They are inquiring as to whether their work will be simplified under the arrangement being sponsored by the administration, whereby they will have to maintain contacts with two Cabinet members instead of one. In addition to this proposed transfer the reorganization sets up a Bureau of Transportation in the Department of Commerce, which is to deal with railroads, waterways and highways.

Due to the large volume of business which must be transacted with the federal government in carrying out the multitudinous activities surrounding construction projects of the magnitude of those provided in the program for the federal-aid highway system, very close co-operation must be maintained by state officials with those of the federal government. For this reason, state highway officials are showing very active interest in the reorganization plan.

In some states the rural population already has importuned the state highway commissions not to agree to the transfer of the Bureau of Public Roads from the Department of Agriculture. In those cases the attitude has been that the highway is a more important factor in the conduct of farming operations than it is to any other activity. The contention is that the Secretary of Agriculture could be relied upon more than any other cabinet officer to champion policies which would give farmers good highway facilities without saddling on them a disproportionate amount of the cost.

Richmond, Va., Seeks Aid for Its Port Development

The city of Richmond, Va., acting through its council committee on dock, river and harbor, has retained the Technical Advisory Corp. of New York to make a port and industrial survey of Richmond and its environs.

The investigation is aimed at two purposes: (1) To secure the aid of the federal government in improving the James River; and (2) to formulate a plan for the industrial development of the city.

As a result of the survey, which was started in September Richmond hopes to convince the board of army engineers and Congress that a substantial appropriation for the improvement of the James River will be warranted. It will be the purpose of the city, if the desired river improvements are made, to provide an adequate modern terminal.

Construction Under Way on Pit No. 3 Project

Half of Railroad Complete—Work on Tunnel Being Advanced — Drilling at Dam Site

Construction is going forward rapidly on tunnel and preliminary work for the Pit River plant No. 3 in northern California. This plant is fourth in the Pit River series which is being built by the Pacific Gas & Electric Co. as power demands on the system require. The location and features of the proposed development as a whole were outlined in *Engineering News-Record*, Oct. 13, 1921, p. 604 and the Pit No. 1 plant was described in the issue of Oct. 5, 1922, p. 570.

The first half of the 10-mile railroad necessary to reach the Pit 3 power house was completed Sept. 1, bringing rail head to headquarters camp at the diversion dam site, which is also the upper end of the four-mile tunnel. The remaining five miles of railroad which involves heavy construction through the Pit River Canyon is to be completed by Jan. 1.

Work on the tunnel is now being advanced from the intake portal, from two portals at Rock Creek, 13 miles below, and at the adit about a mile below Rock Creek. Work at the lower end will not be begun until the railroad reaches that point. On Oct. 20 the intake heading was in about 600 ft. The tunnel is being excavated to a 21x21-ft. horse-shoe section; it will be lined with concrete and will probably require timbering for most of its length. The first 600 ft. was largely through volcanic tuff and diamond drilling indicates that the same material will be encountered for another 600 ft. after which lava and basalt are expected.

CONTRACTOR FURNISHED EQUIPMENT

In order to insure having equipment on the job suitable for the several tunnels contemplated in this vicinity the power company decided to furnish the contractor on this tunnel with all heavy equipment, such as compressor plant, steam shovels, muck cars, etc. and to build such camp structures, roads, railroads, inclines, etc. as may be required. Small tools, drill steel, power, etc., are to be furnished by the contractor. Under this plan of operation it will not be necessary to let the work in such large blocks. Contract for a total of 2,000 ft. of tunnel at Rock Creek and the adit now under way is held by the Bates & Borland Co. The power company is driving the intake heading with its own crews.

Diamond drilling at the dam site indicates that foundations will go about 25 ft. below stream bed. A gravity-type concrete dam 125 ft. high is contemplated. While foundations are being placed the stream is to be carried in a flume about 12x30 ft. in section and 1,200 ft. long of which the upper 800 ft. at the dam site probably will be made of concrete as a safeguard against interruptions during the short low-water season. The capacity of the flume will be 3,000 sec.-ft., this capacity being about 20 per cent in excess of the normal low-water flow. Half of the heavy rock cribs for the temporary diversion dam are now in place; the remaining cribs will be placed in April or May of next year.

Pit River No. 3 power house is to contain three 27,000 kva. generators

Mersey River Tunnel Proposed

A project for a highway tunnel under the River Mersey to connect the cities of Liverpool and Birkenhead, England, provides for a single bore 44 ft. inside diameter. It would be located a little downstream from the Mersey Ry. tunnel, and would have a river length of about 4,000 ft., with long approaches or grades of 5 per cent for light traffic and street cars and 3 per cent for a lateral approach carrying heavy traffic of the docks district. At the centerline of the tunnel section would be a 36-ft. deck wide enough for four lines of vehicles and two narrow sidewalks. Two supporting walls for this deck would form a central section for street cars and two side sections for ventilating

PROPOSED MERSEY RIVER TUBE

ducts. About 17 ft. above the upper deck would be a flat roof or ceiling forming an air exhaust duct along the top of the tunnel.

It is proposed to have a cast-iron shell with interior concrete lining and with grout pumped to fill all exterior voids. The total cost is estimated at \$32,000,000. The consulting engineers are Sir Maurice Fitzmaurice, Basil Mott and John Brodie.

Legal Obstacles Removed in Extending Minidoka Project

Extension of the Minidoka reclamation project in Idaho to overflow part of the present site of the town of American Falls may proceed, legal obstacles having been removed by the decision of the Supreme Court Nov. 12 in the suit of DeWitt Garrison Brown and Rosa C. Brown against the United States.

Because extension of the project would inundate part of American Falls, a town of 1,500 inhabitants, Congress passed a special act authorizing the Reclamation Service to condemn land adjoining the town to which land three-fourths of the town would be removed. Proceedings were begun to condemn a farm owned by the Browns. The jury awarded them \$6,250 and, under Idaho law, \$328 for interest. The Browns resisted and filed suit to resist the condemnation on the ground that the proposed use of their land did not constitute public interest. This contention the Supreme Court held to be wholly erroneous.

driven by vertical reaction wheels operating under a static head of 313 ft. and is to be in service Oct., 1925. Construction work on the project is under the direction of O. W. Peterson.

Non-Partisan Board Selects New New York Roads

Approximately 1,000 miles of new state highways will be added to the New York State system of good roads during the next eight years if the program approved by a non-partisan committee, named by Col. Frederick S. Greene, superintendent of public works, of New York State, be approved by the legislature. The committee named is as follows: H. Eltinge Breed, representing American Society of Civil Engineers; W. F. Wilson, representing County Highway Superintendents Association; C. W. Hawes, representing Dairymen's League; C. O. Kramer, representing Motor Truck Association of America; Charles W. Leavitt, Jr., representing New York State Association of Real Estate Boards; Frank M. Baucus, representing New York State Automobile Association; F. J. Riley, secretary, New York State Grange; B. W. Miller, representing Federation of Farm Bureaus; and T. H. Bennet, representing Motor Federation.

The committee met at Albany on Nov. 20 and approved a majority of the proposed development, cost of which is estimated at from \$45,000 to \$50,000 per mile. About 400 miles of additional roads are still to be approved and will be considered by the committee at a meeting Dec. 11.

Colonel Greene, in opening the meeting, told the committee that it was to have the entire say in the selection of the roads proposed by his department, county superintendents of highways and division engineers.

"The highway department will not have a vote in the matter" said he. "What we aim to do is to stop building roads to placate those who have political power and to end the construction of deadhead highways."

To bring about a consummation of the plans for the additional roads, legislative enactment will be necessary including a change of the map of the ultimate system of state and county highways and an amendment to the highway law inserting therein the new routes proposed.

Railroad Denied Right-of-Way in Salt Creek Oil Fields

The Department of the Interior has denied a right-of-way across the Salt Creek oil fields in Wyoming to the North & South Railroad Co., a new railroad 332 miles long now building from near Casper, Wyo., in Miles City in Montana. The reason for the denial of the right-of-way across 20 miles of the Salt Creek field is based on the fact that the public lands in the Salt Creek field have been reserved and that, because of this reservation, the law does not sanction the building of a railroad across it. Another ground for the refusal to approve the map as submitted by the North & South Railroad Co. is the fact that the railroad would interfere seriously with the development of oil in the fields and the rights of the oil lessees, according to the Department of the Interior. As one of the chief objects in building this railroad was to provide the oil fields of the Salt Creek area with an outlet, it is probable that a way will be found to circumvent the technicalities now standing in the way of this construction.

Federal Employees Protest Personnel Classification

Washington Correspondence

A storm has been precipitated by the action of the Personnel Classification Board in reversing its attitude toward tentative reclassification of civilian employees of the federal government outside the District of Columbia. Following a mass meeting in Washington, a committee representing the National Federation of Federal Employees sent a formal protest to the board and asked President Coolidge to order an investigation, declaring that the reclassification act was being disregarded. The change in policy by the board affects only federal employees outside the District of Columbia. In preparing a report for Congress regarding reclassification of these employees, the field division of the board, under the board's instructions, prepared specifications for the various kinds of work and called for allocations by heads of divisions under these specifications, whereby the same rates of pay would be given for comparable work and responsibility regardless of the department or place where this work is performed. With about 60 per cent of the reports at hand, the division sent a tentative report to the Budget Bureau for its information in formulating departmental and bureau budgets for 1925. The District of Columbia Division proceeded differently, classifying employees by departments and bureaus according to present duties and pay, leaving for the future the specifications for comparable work by which inequalities will be removed. The District schedule is to go into effect July 1, next, while the law called for a report, only, as to the field forces.

On Nov. 13, the Board, by a vote of two to one, directed that estimates be prepared for the field forces on the same basis as was used in the District of Columbia Division in order that more complete estimates of cost might be at hand in the event Congress did not provide a bonus for field workers.

Levees and Drainage for the Arkansas River

Reclamation of the overflowed lands along the Arkansas River in Kansas is of increasing importance to the industrial development of cities along the river as well as to agricultural development, and a co-operative movement for such work has been taken by the organization of the Arkansas Valley Improvement Association to co-ordinate the various interests and communities and to assist in organizing a number of drainage districts to carry out the works. Levees and bank protection are needed, and ditches and levees to take care of the runoff from hill streams whose natural channels are of insufficient capacity. One most perplexing problem is the reconstruction of bridges in and adjacent to the larger cities, such as Wichita, Larned, Hutchinson and Arkansas City, since the majority of these bridges are inadequate to pass flood discharges. R. H. Rhoads, Arkansas City, Kan., is secretary of the Association and the Clark E. Jacoby Engineering Co., Kansas City, Mo., acts as consulting engineer. This company has already submitted plans for flood control at Wichita, Kan., and for levee works at Larned.

Ford Bid for Muscle Shoals Gains in Favor

With the chairman of the Appropriations Committee of the House of Representatives actively advocating the acceptance of the Ford offer for the government's properties at Muscle Shoals, the prospect of the acceptance of that offer by Congress is increased. Entirely apart from the importance of his position, Chairman Madden possesses powerful influence among the conservative Republicans, the portion of the House membership relied upon to defeat the Ford bill.

In conversation with the Washington correspondent of *Engineering News-Record*, Mr. Madden admitted that he is not informed as to the important offers for Muscle Shoals which are said to be in prospect but he reiterated his belief that Mr. Ford is in a better position than anyone else to develop that property. Mr. Madden confirmed the statement carried recently by the Associated Press, to the effect that he is backing the Ford offer principally because of its fertilizer feature, under which Mr. Ford would be required to make an immediate investment of some \$50,000,000. The government can afford, Mr. Madden believes, to write off its expenditures at Muscle Shoals if it assures the farmers adequate supplies of fertilizers at low cost.

Southern Pacific to Complete Double Track Over Sierras

The Southern Pacific Co. is now completing the double tracking of its main line over the Sierra Nevada Mountains. This involves the building of a new second track from Blue Canyon to Truckee, a distance of about 41 miles. Portions of this new work, from Blue Canyon to Emigrant Gap and from Andover to Truckee, totaling 12.7 miles, have recently been completed at a cost of about \$1,200,000. The final section from Emigrant Gap to Andover, a distance of 28.7 miles, will cost about \$10,000,000, or an average cost for the 41 miles of about \$290,000 per mile. Double tracking on this section of the line has been left until the last because it involves the heaviest construction in the mountains. The completion of this project, which is expected in about two years, will give a continuous double track from San Francisco to Sparks, Nev.

Throughout this double-track work improvements have been introduced in the form of reduced curvatures and decreased lengths of snow sheds. About two miles of the second track at the summit will be on a newly located line in tunnel under Donner Peak. This new location which will be used by eastbound traffic will lower the summit by 135 ft. The existing main line over the tunnel will continue to be used by westbound trains. Several short tunnels will also be driven for the second track, the one between Donner Lake and Cold Stream being 877 ft. long.

Other features of the work are three steel viaducts as follows: Across Butte Canyon 410 ft., across Lower Cascade 103 ft. and across Upper Cascade 298 ft.

Grading and tunneling on the new work will be done by contract; viaduct and track work will be done by the railroad under the direction of G. W. Boschke, chief engineer, and W. H. Kirkbride, engineer maintenance-of-way.

China Relief Commission to Construct Utilities

American Engineer to Be in Charge
of River Control and
Highway Work

Oliver J. Todd, a member of the American Society of Civil Engineers, has been appointed by the executive committee of the China International Famine Relief Commission to take charge of the engineering work of the commission in North and Central China. This commission was organized in the fall of 1921 to take over the work of six or eight organizations which have been handling famine relief work during and after the great famine of 1920-21. It took over the funds of these several commissions and is now using the unexpended balance as a revolving fund for river-control work and for highway construction throughout the provinces of North and Central China, where the menace of flood and the lack of highways are the contributing causes to famine.

The new program contemplates immediate investigations and surveys of various public utility projects, such as river control for the Yellow River and other large streams, irrigation projects, and an extensive network of highways. This will necessitate the establishing of local engineering bureaus in each of the provinces where the commission will carry on its work. In these local bureaus Chinese engineers will be employed and their work directed by the Peking headquarters. The Peking office will be in charge of Mr. Todd and he will have two or three American engineers as assistants and also several Chinese engineers who have been working with him in China during the past four years. It is expected that some of the river-control work will be started in the spring as famine-prevention measures and other work such as highway extensions will be undertaken only as relief measures in districts where subnormal crops make some relief desirable. The commission expects to continue its policy of employing famine sufferers on this work and paying them in grain.

Additional funds for the prosecution of this work will be raised in two ways: First, by annual contributions from Chinese provincial relief societies, and second, by having a portion of the new customs increase of the Chinese Government allotted to the work of the commission when the increase is approved. It is estimated that about \$750,000 a year will be available.

Belle Isle Bridge Opened

Detroit's new \$3,000,000 Belle Isle bridge connecting the main land with Belle Isle was formally opened to traffic on Nov. 1, following ceremonies and a parade across the bridge, which marked the close of 27 months in building and 25 years' agitation for a new structure. At the conclusion of the ceremonies, a procession estimated at 10,000 people crossed the bridge on foot.

H. H. Esselstyn, engineer in charge of the construction of the bridge presented the bridge to John W. Reid, commissioner of public works. Tribute was paid to Greiling Bros., builders of the bridge.

Reclamation Advisers Believe Settlers' Relief Necessary

Washington Correspondence

Witnesses appearing before the Special Advisers on Reclamation apparently have been convinced that body that prompt relief must be found for some of the projects. Governor Campbell, chairman of the advisers, suggests that some type of moratorium may have to be arranged. At the initial conference with the press last week, Governor Campbell pointed out that the work of the advisers thus far largely has been along the lines of research. Enough testimony has been heard, however, to convince Gov. Campbell that something must be done promptly to reorganize the fiscal principles under which the reclamation projects are being operated. Despite the rather hopeless situation in which many of the settlers find themselves, Gov. Campbell declared the demand for repudiation is negligible.

One of the points brought out by witnesses before the advisers is the matter of the efficiency of the individual farmer. Under the law no selective process can be employed in the choice of settlers. Apparently there is a new realization that the success of a farming enterprise on a reclamation project depends to a greater extent than on the average farm on the ability of the individual farmer. Inclusion of land of doubtful value is a source of weakness in some projects, the evidence presented by witnesses would indicate. Other witnesses contend that construction costs are excessive. All agree, however, Chairman Campbell stated, that the work is well done, but some contend that it is done too well.

Formulate Principles to Underlie Building Trade Apprenticeships

General principles which it was agreed should underlie apprenticeship training in the building trades were formulated at a conference in Washington Nov. 15 between the Federal Board for Vocational Education and representatives of employers and employees and material supply manufacturers.

Eight general principles were laid down. They are:

- 1.—That a local representative committee composed of all interests in the industry is essential to determine the needs and supervise the training.
- 2.—That part time or evening schools should be provided to supplement job training.
- 3.—That all-around training is more desirable than specialized training.
- 4.—That the national associations should set up fundamental training standards for apprentice training and make the information thereon available for instructional purposes.
- 5.—That co-operation with the public schools is essential to the promotion of apprentice education.
- 6.—That incentives should be set up to induce boys to enter apprenticeship.
- 7.—That pre-employment training for employed apprentices or boys under contract is recommended.
- 8.—That emphasis should be placed on full-season training to follow up the initial training given in the pre-employment period.

A number of those attending the conference, which was called for discussion of the apprenticeship problem rather

than for immediate definite action, recited plans which have been followed in various trades at specific localities to induce more young men to enter apprenticeship, or which have been devised to be put into operation soon.

N. Y. Central Offers Plan To Solve West Side Problem

The New York Central R.R. has offered a plan to the Transit Commission of New York City whereby solution of its so-called West Side trackage problems is to be accomplished through elimination of tracks from city streets, increase in freight transportation facilities and abandonment of certain terminal structures and track. Principal features of the proposed reconstruction, which, with grade crossing elimination it is estimated will cost \$75,000,000, are a two-track elevated line from the new terminal at West and Spring Sts. to the 30th St. yards (which are to be double-decked); a four-track elevated line from 30th St. to 59th St., and from there widening of the right-of-way to allow installation of five tracks to another elevated structure at 116th St.

City Managers Hold Convention

Discussion of literally scores of problems which confront city managers constituted the feature of the tenth annual convention of the City Managers' Association, held recently in Washington, D. C. The discussion was divided into three parts, dealing with problems common to communities of 15,000 population, of 10,000 population and of 5,000 population. Particular interest was shown in markets, trees, lights, zoning, disposition of refuse, and water supply. Parks, bridges, schools, hospitals, reformatories and the various city departments were visited. A considerable portion of the time of those in attendance at the convention was spent on inspection trips.

Joint sessions were held with the National Municipal League and the Government Research Conference.

To Seek Aid for Government Barge Lines

Washington Correspondence

An effort will be made at the forthcoming session of Congress to secure legislation which will provide a new basis for the operation of Government barge lines. The Secretary of War now is considering the draft of the bill which would provide the Mississippi-Warrior services with a larger amount of working capital. It also provides that while the management still is to be vested in the War Department, it will be freed from departmental restrictions so as to be able to exercise a control similar to that employed in private enterprise. If the management can be arranged so that it may have the advantage of more direct control, it is believed a much better showing can be made.

A determined effort will be made at this session of Congress, it is understood, to set up a policy which will permit the War Department to do pioneering in inland waterway transportation on other streams. An argument which will be advanced in support of the plan is that this provides a cheaper way of expanding transportation facilities than would the construction of additional rail facilities to handle an equivalent tonnage.

Random Lines

Brothers Under Their Skins

"There is a demand in the church for a new type of worker—the 'socio-religious engineer', D. J. Beebe, dean of the school of theology, Boston University, declared today at the annual meeting of the board of home missions of the Methodist Episcopal Church. The 'socio-religious engineer', the speaker said, has special skill in relating the church to the whole life of the community and can deal with community problems from the religious point of view."—From the Boston Herald.

Now if he could only fix up a partnership with our old friend the "hymn book engineer," they ought to get most of the business in their line.

* * *

A Live Profession

The propaganda of our brothers the exterminating engineers might well be emulated by some of the older branches of the profession.

They have one virtue, certainly; they get publicity. All over the country the newspapers are carrying their advertisements, but more than that they are getting free advertising

—such as this column gives, for instance. And we find a department editor of the Duluth Herald rather timorously assuring a correspondent that "it would be stretching the term to call this kind of a job a 'profession'". Profession or not, it has a nice new seal, which is shown in the accompanying reproduction.

* * *

The Triumph of the Concrete Ship

The 3000-ton concrete ship "Sapona," built at Wilmington during the war, has achieved a notable end. She has been bought by a Florida hotel keeper and will be located on Ajax Reef, 24 miles south of Miami Beach. The owner is going to fit her out with a "reasonable amount of furniture and equipment and use her as a fisherman's club house." And Bimini only 60 miles away.

* * *

Every Man To His Job

NOTE: An attempt by an engineering society to get its members to write an engineering short story or novel by offering substantial prizes has met with disappointing results.

The engineers, they have no fears. They wear thick leather pants. They spend their time in tropic clime And live in wooden shanties. Meanwhile just look, on screen, in book Is told their tale romantic By scribblers gay so dumb that they Drive engineers near frantic. But why in hell cannot they tell These tales like any other? The fact remains, they lack the brains Or find it too much bother.

BON.

To Build New Power Plant at Montreal

As the result of an agreement between the city of Montreal and the Bank River Power Co. whereby the power company will provide the necessary protection for sewer outlets on the Riviere des Prairies as well as the streets abutting on the river, the power company will now be able to proceed with the construction of a dam below Cedar Island, at which is planned to develop 50,000 hp. An order-in-council was passed by the legislature during its last session authorizing the company to undertake this work as soon as it had reached an agreement with the city of Montreal and had satisfied the Provincial Board of Health that the diversion of the stream would have no injurious effects on public health.

The construction work will include numerous dikes and a dam 1,300 ft. long containing ten 40-ft. sluices for use at times of flood. A 300-ft. channel will be provided on the Montreal island side of the river.

clinical divisions of the society, closer relations with new chapters and local sections, the quarterly meetings and special committees on such subjects as engineering education, and finally the duties of the individual engineer as a citizen. Representatives of the student chapters at Leland Stanford, Jr. University and the University of California asked for the aid of the society and the local section in giving undergraduates a practical view of engineering activities in general. C. D. Marx and C. E. Grunsky supplemented Mr. Dunlap's remarks, referring to past and future activities and endeavors of the society.

Personal Notes

W. Z. BETTS, maintenance bridge engineer for the North Carolina State Highway Commission, has been appointed purchasing agent of the commission to succeed H. V. Joslin.

J. R. WENDT, district maintenance superintendent for maintenance district 8 for the State Highway Commission of Louisiana, has been transferred to Ruston, La., as maintenance superintendent for districts 8 and 9, relieving Fred D. King of district 9, resigned.

C. C. HEZMALHALCH has been appointed deputy state engineer for Colorado, succeeding R. G. Hosca who resigned to enter the automobile business at Fort Morgan. Mr. Hezmalhalch has been a member of the state engineer's staff since 1911.

C. B. ZORN, who has been with the Iowa State Highway Commission for several years, has been appointed county engineer for Monona County at Onawa, Iowa.

GEORGE J. CALDER, consulting engineer, has opened an office at 1010 Eighth Street, Sacramento, Calif., with M. W. SAILBERG, designing engineer, in charge.

T. C. CARHART and JOHN G. STUPP, sales manager and chief engineer of the St. Louis Structural Steel Co., have resigned and entered the structural engineering business as Carhart & Stupp, with offices in the International Life Bldg., St. Louis, Mo., to engage in the design of buildings and structures for industrial plants.

THOMAS SHANKS of Ottawa, Ont., has been appointed assistant director-general of surveys, a new position in the Department of the Interior of Canada.

R. HOME SMITH, chairman of the Toronto, Ontario, Harbor Commission, has resigned.

VAN CAMP, recently assistant engineer for Tarrant County at Ft. Worth, Texas, has been appointed resident engineer in charge of construction of roads in the National Forest at Mena, Ark., under the U. S. Bureau of Public Roads.

T. H. WEBB, assistant state highway engineer for Texas, has been appointed county engineer of Callahan County in charge of a \$500,000 highway improvement program at Baird, Texas.

J. B. RIEMAN has resigned as county engineer of Red River County, Texas, and has been appointed county engineer of Hopkins County.

F. E. DELVIN, consulting engineer, Wichita, Kans., has opened a branch office at Dalhart, Texas, with James Rady as local manager.

A. W. CAMPBELL, chief commissioner of highways of Canada, has gone to England to attend the Public Works, Roads and Transport Congress and exhibition to be held in London this month.

A. P. DAVIS, former director of the U. S. Reclamation Service, has been retained by the City of Los Angeles as consulting engineer in connection with studies of water and power developments which the city has under consideration.

H. V. JOSLIN, purchasing agent of the North Carolina State Highway Commission, has resigned to accept a position as engineer in charge of construction with the Carolina Power & Light Co., Raleigh, N. C.

ERNEST S. MALTICE, formerly managing director of the Phoenix Bridge and Iron Works, Ltd., Montreal, has been appointed chief engineer of Canadian Vickers, Ltd., which recently took over the Phoenix company.

J. L. SIMPSON, British architect and builder, is touring the United States and Canada studying industrial building methods. During his New York visit he was the guest of the John W. Ferguson Co.

GEORGE MCNUTT, construction engineer, North Carolina State Highway Commission, has accepted a position as superintendent of highway construction in North Carolina for the Public Service Corp., of Newark, N. J.

W. R. JOHNSTON, JR., of Maplewood, N. J., has been made terminal engineer of the Lehigh Valley, R.R. He was previously assistant engineer on the Delaware, Lackawanna & Western R.R.

E. PAUL FORD, city engineer of East San Diego, Calif., has resigned, the consolidation of East San Diego with the city of San Diego having been ratified by election on Oct. 23. Mr. Ford will locate in the East.

DENHAM, VAN KEUREN & DENHAM is the new firm name of the consolidation of E. B. Van Keuren & Co., engineers and architects, and William L. Denham and George E. Denham, all of Birmingham, Ala., for the practice of architecture and engineering, with offices in the Herald Bldg., Birmingham.

A. G. MOTT, who has been an assistant engineer in the transportation division of the California State Railroad Commission, has been appointed transportation engineer, succeeding H. G. Weeks, resigned. Mr. Mott is a graduate of Stanford University and for eleven years was employed in various capacities by the Southern Pacific Railway Co.

H. G. WEEKS, transportation engineer of the California State Railroad Commission, has resigned to become assistant to the general manager of the Los Angeles Railway Corp. Mr. Weeks, who has been with the commission since 1913, has dealt with appraisals and rate proceedings, notably

Engineering Societies

Calendar

Annual Meetings

AMERICAN ASSOCIATION OF STATE HIGHWAY OFFICIALS. Washington, D. C.; Annual Convention, New Orleans, La., Dec. 3-6, 1923.

FEDERATED AMERICAN ENGINEERING SOCIETIES. Washington, D. C.; Annual Meeting, Washington, D. C., Jan. 10-11, 1924.

AMERICAN ROADBUILDERS' ASSOCIATION. New York City; Annual Convention, Chicago, Jan. 14-18, 1924.

AMERICAN SOCIETY OF CIVIL ENGINEERS. New York City; Annual Meeting, New York, Jan. 16-18, 1924.

ASSOCIATED GENERAL CONTRACTORS OF AMERICA. Washington, D. C.; Annual Meeting, Chicago, Ill., Jan. 21-23, 1924.

AMERICAN CONCRETE INSTITUTE. Detroit, Mich. Annual Meeting (20th anniversary), Chicago, Ill., Feb. 25-28, 1924.

The Engineers' Club of Philadelphia, on Nov. 20 tendered a dinner to Charles M. Schwab, recently elected an honorary member of the club. The speakers were Dr. Robert H. Fernald, Alva B. Johnson, J. Hampton Moore, Mayor of Philadelphia, Admiral A. H. Seales, Julian Kennedy, and Mr. Schwab. The dinner was made the occasion for presenting Mr. Schwab with the certificate of honorary membership in the club. The other living honorary members are Thomas A. Edison, General George W. Goethals, Edgar F. Smith, Herbert Hoover, and Lewis H. Haupt.

The San Francisco Section, Am. Soc. C. E., held a special meeting on Nov. 14 for Secretary Dunlap, who spent one day in San Francisco in the course of his tour visiting western sections. Mr. Dunlap spoke vigorously and enthusiastically about the formation of tech-

the Los Angeles union terminal and grade crossing elimination cases.

HENRY H. QUIMBY, chief engineer of the department of transit, Philadelphia, Pa., in charge of the planning, construction and equipment of the new municipal high-speed lines, has resigned to engage in private practice.

H. C. FOSTER, formerly associated with the California State Highway Commission, has become affiliated with the Industrial Testing Laboratory of Los Angeles as engineer in charge of road construction.

ANDREW J. O'REILLY, consulting engineer, St. Louis, Mo., has been re-appointed a member of the Missouri Public Service Commission. Mr. O'Reilly's new term will expire in 1929; he was originally appointed to fill out the unexpired term of Edward Flad, who resigned from the board about two years ago.

RAYMOND JONES, of the firm of G. W. Jones & Sons, Huntsville, Ala., has been appointed highway engineer for Limestone County, Alabama.

A. C. LINDLEY, engineer of construction work of the Missouri State Highway Commission, has resigned to engage in the road contracting business with LEWIS RICH of Kansas City, Mo.

GEORGE W. DUNCAN, Jr., formerly with Leland & Hale, consulting engineers of San Francisco, Calif., has become associated with Albert A. Coddington, consulting mechanical engineer, and they will operate under the firm name of Coddington & Duncan, with offices in the Phelan Bldg., San Francisco.

Obituary

CHARLES A. BIGGER, assistant director of the geodetic survey of Canada since 1905, died suddenly of heart disease at Ottawa Nov. 9 in his 71st year. He was born near Paris, Ont., and for many years practiced as an engineer in Ontario and the West. In 1901 he entered government service and conducted surveys of the international boundary.

LYMAN P. HAPGOOD, former superintendent and since 1922 consulting engineer of the Jamestown, N. Y., water and lighting plants, died Nov. 14 after a long illness. He was 47 years old. Mr. Hapgood was a graduate of the Massachusetts Institute of Technology, class of 1899.

THEODORE C. LINK, architect who designed the St. Louis Union Station, the Washington University medical buildings and several of the buildings at the Louisiana Exposition in St. Louis in 1904, died of pneumonia at Baton Rouge, La., Nov. 12 at the age of 73 years. Mr. Link was supervising the erection of a group of buildings for the new Louisiana University and Greater Agricultural College at Baton Rouge, the projects aggregating \$3,000,000. He maintained an office in the Chemical Building, St. Louis. He was born in Germany and educated at Heidelberg, London and Paris.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Is Time for Preparing Bids Too Short?

In the Nov. 8 issue of "Engineering News-Record," p. 783 a manufacturer of waterworks equipment deplored the insufficiency of time usually allowed for preparing estimates or bids on proposed work. Manufacturers of other products used in the construction field expressed their views in the Nov. 22 issue, p. 866. Additional replies follow.—EDITOR.

Cranes

BY A. H. McDUGALL
Whiting Corp., Harvey, Ill.

WE have experienced the same difficulty when bidding on government and municipal work.

With reference to government bids, we have often received notice that bids would be received at a certain time and we would not have time to write to get specifications back and submit a bid. Sometimes there is not time even to receive the specification.

I feel that a great deal of this is due to the time that is taken up in elaborately preparing specifications and drawings for the work. Then the one for whom the work is to be completed gets in a terrible rush over the delay and therefore shortens the time for receiving the bids.

Water Meters

BY J. B. KIRKPATRICK
Neptune Meter Co., New York.

I BEG to advise that the Neptune Meter Co. is not complaining about the shortness of time available for the submission of estimates or bids on proposed contracts.

Cast Iron Pipe

BY D. B. STOKES

U. S. Cast Iron Pipe & Foundry Co.,
Philadelphia

WE have not experienced any trouble along the lines of insufficient time for preparation of estimates or contract bids. Probably the fact that a larger portion of our product for municipal use is made in accordance with the American Water Works Association specifications explains this. Were the material of more intricate design we might require more time to properly prepare a bid.

Automobile Production

Automobile production during the month of October totaled 360,924 cars and trucks, according to reports made to the National Automobile Chamber of Commerce. The total production of cars and trucks for the first ten months of 1923 has been 3,388,785 as compared with 2,119,111 for the same month of last year.

Gen. Tripp Honored by Japan

The government of Japan has conferred the second degree order of the Sacred Treasurer upon Gen. Guy E.

GUY E. TRIPP

Tripp, chairman of the board of the Westinghouse Electric & Manufacturing Co. This is the highest decoration that can be awarded a civilian foreigner by the Japanese government.

General Tripp is in Japan at the present time in connection with reconstruction work

following the recent severe earthquake, and his decoration was in recognition of his activities in assisting the Japanese officials in rebuilding the devastated area. During the World War he served as assistant to the Chief of Ordnance with rank of brigadier general. For meritorious service in this position the Distinguished Service Medal was conferred upon him by the President of the United States.

Brick Makers Will Produce Large Stocks for Next Season's Work

Not since the war, according to the monthly statement issued Nov. 1 by the Common Brick Manufacturers' Association, have the brick men gone into the closing months of the year with such determination to pile up stock as is manifested in current reports of 132 manufacturers doing business in 43 states. The situation on the Hudson River, which provides the brick supply for Greater New York operations, is indicative of what is going on in all the large brick-producing centers. By the time Hudson River navigation opens next spring it is anticipated that the plants along the river will have 600,000,000 brick ready for shipment to their markets. This is 50 per cent greater than the winter stock in any recent year.

Plants are running at full time and will continue until freezing weather stops operations. Those plants equipped for winter running will continue throughout the interim before the coming season. These preparations are going on with the New York manufacturers in spite of the fact that quantities of foreign brick still lie on barges at the docks and many more millions of brick are on their way from Holland and Germany.

Reeves Heads Trade Executives

At its convention in Chicago last month the American Association of Trade Executives elected as its president Alfred Reeves, general manager of the National Automobile Chamber of Commerce. This organization consists of the managers or other executive officers of 158 trade associations.

A Space-Saving Office Partition

To save space in office buildings a new type of 2-in. solid plaster metal-lath partition has been designed by the Sweetland Co., Cleveland, in co-operation with the Cleveland Association of Building Owners and Managers and the Associated Metal Lath Manufacturers. Economy of erection is one of the advantages claimed for this partition.

The details of its construction are shown in the accompanying drawing. Attention is directed to the fact that the wood grounds may be nailed together by long nails, bent over and clinched. The drawing shows the grounds wired to each side of the stud.

If picture molding or cornice is erected at, instead of below, the ceiling

EASILY REMOVABLE PARTITION FOR OFFICE BUILDINGS

Claim Infringement of Pneumatic Concrete Placing Patent

Suit has been brought in the United States Court in New York for the infringement of the MacMichael patent No. 1,127,660 of Feb. 9, 1915, by the Concrete Mixing & Conveying Co. against the Ulen Contracting Co. on account of the use by the defendant of pneumatic concrete conveying and placing machines in the Shandank tunnel of New York City's Catskill aqueduct. The development of this system by MacMichael dates back to 1907, when the application for the patent under which suit is brought was filed.

The apparatus involved in the infringement is known as the Webb-Cox

Pan-Americans to Inspect U. S. Roads and Transport

Trip for Forty Delegates Arranged by Automotive, Road Machinery, Financial and Government Interests

FORTY delegates will be brought to this country from Pan-American countries to make an intensive study of highways and highway transport under the terms of a plan approved by government, automotive, road machinery, road material and banking representatives at a meeting held in New York, Nov. 22. The proposal as outlined by J. Walter Drake, Assistant Secretary of Commerce; T. H. MacDonald, chief, U. S. Bureau of Public Roads, and Dr. G. Sherwell, secretary-general of the Inter-American High Commission, provides that the men to be invited will be named here, and all of their expenses will be paid by private subscription.

The immediate purpose is to give the delegates a sufficient understanding of developed highway transport to enable them to participate actively in the Pan-American Highway Congress proposed at the last meeting of the Pan-American Union and which will be held as a separate project next year. The ultimate objective is the promotion of closer relations between the United States and the other countries of the Americas.

Roy D. Chapin, Hudson-Essex Co.; W. A. Beatty, Austin Manufacturing Co., and Fred I. Kent, Bankers Trust Co., were named as an executive committee. Details in this country will be handled by the Highway Education Board. S. T. Henry, Allied Machinery Co. of America, will manage the project.

The motor industry was represented at the meeting by Roy D. Chapin, vice-president of the National Automobile Chamber of Commerce; Alfred Swayne (General Motors); A. J. Brosseau (Mack); and Alfred Reeves, George Bauer and Pyke Johnson of the National Automobile Chamber of Commerce.

Cement Industry Worked at 20% Below Capacity in 1921

Cement manufacture during 1921 was at a rate more than 20 per cent less than the capacity of the industry. Had conditions been such as to make maximum output possible, cement to the value of \$259,015,207 would have been manufactured during that year. Instead the value of the output of the 125 cement plants of the country was \$203,626,929, or 78.6 per cent of the possible output.

These figures have just been made public by the Bureau of the Census. They were compiled as a result of recommendations by the Committee on Census Schedules, created at a conference of trade associations which met in Washington in 1921 at the instance of the National Association of Manufacturers. Nathan B. Williams was chairman of the committee.

Paving materials manufacture was at a rate slightly greater than half the capacity of the industry to produce. Had conditions in that industry been such as to make possible maximum output paving materials to the value of \$101,724,458 would have been produced. As it was, the value of products aggregat-

line it may be advisable to have a 2x2-in. buck at the ceiling. The channel studs may be attached to the floor buck by boring holes $\frac{3}{4}$ in. in diameter in the buck and inserting the stud in these holes. This method saves bending the stud. It is essential to have a steel channel stud on each side of the door buck.

plaster, and operates in the tunnel to shoot the concrete dumped therein along a conduit by the action of compressed air and place it around the forms for the tunnel lining. Suits against other infringers are expected to follow.

Material-Handling Equipment To Be Shown at Power Show

Material-handling equipment will be a new feature of the second National Exposition of Power and Mechanical Engineering to be held at the Grand Central Palace, New York, Dec. 3-8. The equipment to be exhibited will include conveyors of all kinds, locomotives, industrial trucks, elevators, hoists and large scales. One exhibitor is to install a working model of a complete system of steel-belt conveyors for handling sticky materials, sharp-edge materials or materials at high temperature. Another manufacturer will show a working model of complete coal-handling equipment in a miniature power house. The model will show a skip-hoist, bunker, coal weigh larry and cable drag scraper. A program of motion pictures showing the application of equipment will be displayed.

The Power Exhibition, held annually, features the development of apparatus for the economical combustion of fuel and the production and utilization of power. The managers of the exposition are Fred W. Payne and Charles F. Roth with offices in the Grand Central Palace.

Trailer Association Would Admit Camping Equipment Makers

The membership committee of the Trailer Manufacturers Association, New York, announces that overtures have been made to the manufacturers of camping trailers in regard to joining the association. The association at present is composed exclusively of makers of commercial trailers. While the camp trailer is a very different vehicle and appeals to a different class of purchaser, the truck trailer men believe that they have enough in common with the camp trailer makers to furnish ground for co-operative work.

Construction Equipment Exported

Exports of construction equipment from the United States during September are shown in figures just issued by the Department of Commerce. During the month there were shipped 53 concrete mixers valued at \$38,999, eleven of these units going to Japan; 3 power shovels, at \$42,195; 185 conveyors, at \$30,298; and 373 hoists and derricks at \$87,296.

gated \$61,128,969, or 58.4 per cent of the possible output.

The percentage of possible output among all of the industries of the country was 56.8. This covers 194,194 establishments, with a combined value of products of \$42,318,241,453. Had these plants worked at maximum capacity, they would have produced, \$74,123,930,736.

Business Notes

NATIONAL STEEL FABRIC CO., Pittsburgh, established on Nov. 1 a dealer sales department in charge of W. H. Shaffer, Jr., who for seventeen years had filled a similar position with the Universal Portland Cement Co. The function of the new department is to promote sales of dealers and to expedite deliveries of materials.

NATIONAL LIME ASSOCIATION, Washington, D. C., announces the appointment of Burton A. Ford as secretary and general manager. For the past three months Mr. Ford has been acting secretary of the association. He is a graduate of the University of Maryland, and until the summer of 1922 was with the Virginia-Carolina Chemical Co. in the capacity of division manager, and was also secretary-treasurer of the Bryant Fertilizer Co. In the summer of 1922 he became assistant to W. R. Phillips, who was then general manager of the National Lime Association.

HARRY MEACHEM, formerly of Dean Bros., Indianapolis, has been appointed vice-president and general manager of the Rider-Ericsson Engine Co., New York.

UNITED STATES CAST IRON PIPE & FOUNDRY CO., Burlington, N. J., announces the appointment of Thomas P. Anthony as chief engineer, with headquarters at Burlington. P. T. Laws has been chosen as the company's Southern district manager, with headquarters at 1002 American Trust & Savings Bank Building, Birmingham, Ala.

CHAIN BELT CO., Milwaukee, manufacturer of Rex chain, concrete mixers and conveying equipment, formerly represented on the Pacific Coast by Meese & Gottfried Co., San Francisco, has established direct factory branches and warehouses in Portland and Seattle. Arrangements have also been made with the Washington Machinery Depot, Tacoma, to carry stocks of chain and transmission machinery. Other stocks will be placed in important centers throughout the Pacific Northwest for the prompt handling of local requirements. The Northwest territory, with headquarters at Portland, will be in charge of Allen C. Sullivan, formerly connected with the Allis-Chalmers Co., Milwaukee, and more recently with Smith & Watson Iron Works of Portland. Don B. Catton, formerly with Meese & Gottfried Co. and later engaged in the machinery supply business on his own account will be the special sales representative for the Portland office. The Seattle and British Columbia territory will be handled by William F. Nichols who for the past 11 years has been with the Meese & Gottfried Co.

Equipment and Materials

Cork Foundations to Reduce Vibration of Machinery

To minimize the vibration of heavy machinery the Korfund Co., New York, has placed upon the market a cork foundation plate of German origin, made of solid blocks of natural cork bound together into rectangular slabs by iron straps and impregnated by a method which is claimed to prevent decay and at the same time preserve the maximum elasticity of the cork. These insulation plates are in the form of rectangles 4 in. thick and 10 x 12 ft. in plan. This type of insulating foundation, the manufacturer claims, not only increases the life of the machine which it supports but also prevents damage to buildings in which machinery is housed. The cork plates may be obtained to fit any size of machinery and any shape of foundation. The company also manufactures a cork insulating plate to be placed between the tie and the rail of a railway track.

Internal-Gear Industrial Tractor

A new storage-battery tractor brought out by the Mercury Manufacturing Co., Chicago, for industrial service in shops, freighthouses and manufacturing plants, differs from the company's previous designs in having an internal gear in-

stead of a worm-gear drive. An increased work efficiency of 25 to 35 per cent is claimed for this design, increased power being accompanied by a decrease in power consumption. A pinion driven by the motor through a flexible coupling drives a bevel gear in the axle housing and this gear in turn drives the axle pinions for the two rear wheels. Each pinion transmits the power through three idler gears to an internal or ring gear on the inside of the rim of the 20-in. driving wheel. With a gear ratio of 18 to 1 the drawbar pull is 475 lb. normal and 1,800 lb. maximum, while with a ratio of 24 to 1 the figures are 600 lb. and 2,100 lb. respectively.

The power unit, including a high-speed motor, is self-contained and can be detached from the machine by removing two bolts. Heat-treated chrome manganese steel is used for all gears. The steel frame carrying the battery box and control apparatus is carried by semi-elliptic springs and four rubber-tired wheels, but the two 15-in. front wheels are mounted on a short axle to give as short a turning radius as a three-wheel arrangement. This radius

is 5 ft. The service brake has shoes bearing on a drum on the motor armature. When the driver dismounts an emergency brake is set automatically by a spring under the seat, the same spring also shutting off the current. A rear coupler is carried by a cast-steel fork attached to the axle housing, so that the pulling strain is taken directly by the axle and not by the frame and springs. At the front end is a combined fender and bumper to protect the driver and to permit of pushing trailers when necessary.

In overall dimensions the machine is 5 ft. 8 in. long, 3 ft. 3 in. wide and 4 ft. high. Its weight is 1,850 lb. without battery and from 2,750 to 3,350 lb. in working order, according to the kind of battery and number of cells. The speed capacity, without load, is 660 and 572 ft. per minute for 18 to 1 and 24 to 1 gear reduction, or 7½ and 6½ m.p.h. respectively.

Publications from the Construction Industry

Metal Lath Data—TRUSCON STEEL CO., Detroit has included in its 48-p. illustrated "Metal Lath Data Book" a mass of information well arranged and clearly expressed, on approved methods and specifications for the use of metal lath in building construction of all types. The information should be particularly valuable to engineers, architects and contractors. The text represents a year's study of the practical uses of metal lath. There are a number of pages of detailed drawings of partitions, walls, floors, roofs, and attached and suspended ceilings. Suggestions also are offered for interior plastering and exterior stucco work. Useful data on loads and properties of Hy-Rib are contained in the form of tables. For all uses of metal lath described and illustrated detailed specifications are given.

Power Shovels—MARION STEAM SHOVEL CO., Marion, Ohio, features its 3-yd. revolving electric and gasoline-electric shovels in a newly issued 16-p. illustrated bulletin. Data are given showing comparative cost of steam, electric, and gasoline-electric operation, and the various mechanical features of the machine are illustrated and described in detail. A feature of the shovel is the use of separate motors for the three main operations of crowding, hoisting and swinging.

Hydraulic Dredging Machinery—MORRIS MACHINE WORKS, Baldwinville, N. Y., features its sand and dredging pumps and hydraulic dredging machinery in a 44-p. illustrated booklet just published. The text includes a discussion of sizes and capacities of hydraulic dredges, the use of hydraulic dredges for the production of sand and gravel and hydraulic mining operations. Detailed illustrated descriptions are given of the company's standard dredge pumps, including models belt-driven, direct-connected to steam engines and motor operated. Part of the text is devoted to auxiliary equipment, such as cutters, agitators, hoists, sheaves and spuds.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for, in *Construction News*, pp. 291 to 303, are the following:

High School, Boston, Mass., Dept. Pub. Wks., \$1,200,000.

Hotel, Birmingham, Ala., T. H. Molton, \$1,500,000.

Dam, Los Angeles, Calif., Los Angeles Co., \$20,000,000.

Gilsonite Constr. Co., \$1,800,000.
Hotel, San Diego, Calif., to Vukicevick & Bagge, San Francisco, \$1,000,000.
Apartment, New York, N. Y., \$1,000,000.

Hotel, Louisville, Ky., to Rommel Bros., \$2,300,000.

Recent Unit Bids Throughout the Country

The accompanying table gives representative bid prices of various materials and operations, applying on a number of the more important contracts awarded during the last month.

A workable acquaintance with construction cost in outlying districts, may be had by studying the unit bids published weekly in the *Construction News* section of *Engineering News-Record*.

Common Brick Imports Increase

Receipts For Last Three Months Gain Heavily Over Preceding Quarter—Domestic Output Heavier

Nearly 19,000,000 common brick were imported into this country, through the Port of New York, during the third quarter of the current year as against 10,379 for the preceding quarter. According to the Bureau of Foreign and Domestic Commerce the actual total was 18,953,000 (valued at \$155,502), 18,365,000 of which came from Holland.

These brick, with few exceptions, conform to the American standard size, i.e., 8 x 3 1/2 x 2 1/4 in., and have not materially affected the domestic common brick quotation, neither have they pene-

Large Contracts Let During Week

Among the weeks announcements of contracts awarded in *Construction News*, pp. 291 to 303, are the following:

Power Plant, Davenport, Ia., United Light and Railways Co., Grand Rapids, Mich., \$10,000,000.

Apartment Hotel, Dallas, Tex., to

trated very far inland, most shipments having been consumed in the New York district.

Common brick in the New York market are quoted at \$19 per M wholesale, alongside dock, as against \$19@20 one month ago. This decline, however, is seasonal and does not reflect the influence of importations.

Brick importations through the Port of New York, during the last quarter, are shown in the following table:

	Number	Value
July:		
Holland	9,443,000	\$74,377
August:		
Canada	100,000	1,380
Holland	3,373,000	26,989
September:		
Germany	63,000	411
Holland	5,549,000	48,420
Canada	425,000	3,925
Total	18,953,000	\$155,502

Reserve stocks of burned and unburned brick, particularly in the New

York district, are 50 per cent greater than winter stocks in any recent year. According to the Common Brick Manufacturers' Association of America, brickyards are running at full time and will continue until freezing weather stops operations. Those plants equipped for winter running will continue operations until spring. These preparations are going on with the New York manufacturers despite the quantities of foreign brick on barges at the docks.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted.

Valuable suggestions on costs of work can be had by noting actual biddings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Nov. 1; the next, on Dec. 6.

Steel Products:	New York	Atlanta	Dallas	Chicago	Minneapolis	Denver	San Francisco	Seattle	Montreal

Explanation of Prices:—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or — signs. For steel pipe, the prevailing discount from list price is given: 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b. labor—Concrete laborers' rate, 93¢; building laborers (pick and shovel men) 75c. per hr.

Chicago: quotations hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis: quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver: quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. Tile price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta: quotes sand, stone and gravel per ton instead of cu. yd. Common lump lime per 180-lb. net.

Dallas: quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco: quotes on Heath tile, size 5 $\frac{1}{2}$ x 8 x 11 $\frac{1}{2}$. Prices are all f.o.b. warehouses except C. I. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir, common.

Seattle: quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal: quotes on white pine lumber, free on cars at mill. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 97.81). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$47.43; 6-in., \$119.

Changes Since Last Week

Increased activity in pig-iron buying is possibly the most favorable factor in the current business situation. Sales, though not involving large tonnages, constitute a marked contrast with the recent dullness in this important commodity.

Rise in cotton prices and a recovery of the foreign exchange are also noteworthy features of the weeks' developments.

Car loadings for the last twenty-one weeks have passed the million mark. A total of 1,036,067 cars were loaded during the week ended Nov. 10. These freight movements indicate heavy dis-

tribution of materials for this time of the year.

The trend of the lumber movement indicates a falling off in production but at the same time a substantial increase in shipments and new business.

Cement prices declined 8c. in Minneapolis and 10c. per bbl. in Chicago, during the month. Similar recessions occurred in eleven other cities in the Middle West.

The Japanese Embassy on Nov. 14, advised the National Lumber Manufacturers' Association, that contracts for 97,150,000 ft. of lumber had already been awarded. Contracts were also let,

during the month, by the Japanese Ambassador, in behalf of the Japanese Government, for 20,000 tons of steel sheets, to the U. S. Steel Corporation; 2,000 tons of wire nails to the Youngstown Sheet and Tube Co. and 1,000 tons of wire nails to the Pittsburgh Steel Company.

Common brick advanced \$1 per M., wholesale, alongside dock New York, making the present price \$19, against \$18@19 per M., one week ago. The advance was evidently due to a general movement on the part of materials buyers, to cover their requirements against a possible Spring shortage.

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING
AND CONTRACTING

E. J. MEHREN, Editor
FRANK C. WIGHT, Managing Editor

Volume 91

NEW YORK, DECEMBER 6, 1923

Number 23

Pity the Poor Editor

THIS is the time of the year when an editor realizes how elaborate is the mechanism of government. In every mail there comes from Washington some new product of the Government Printing Office. Yesterday it was the special press copy of the annual report of the Corps of Engineers (printed on one side of each sheet only, 6½ in. thick and weighing 8 lb. 2½ oz.); today it is the more modest report of the Shipping Board, the not yet to be released message of the President to Congress, three minor bureau reports and a long abstract of what the Chamber of Commerce of the United States thinks Congress should do in the next month or six weeks. Tomorrow several of the Cabinet officers will submit their annual accountings, accompanied in each case by nicely abstracted digests for press consumption, all signed, if not read, by the member of the cabinet whose ostensible words are so recorded. The mere reader is fortunate. Much of this verbosity finds the waste basket and that which survives suffers a diminution which must pain the official authors. Pity the poor editor, who can not so easily avoid his irksome task of finding out just what the government at Washington does to insure that the republic still lives.

Responsibility

THOUGH investors had paid in \$282,000, receivers for the Federal Home Building Corp. of St. Louis found that the organization had only \$1.92 in cash, a bank balance of \$127.12 and a \$50 Liberty bond, as liquid assets. Contract holders for whom not even plans had been drawn, and who had been promised residences at a cost lower than any contractor would quote, had paid \$123,608. The receivers' audit showed practically no construction work done for the 400 contract holders. It is not often one can reduce to dollars the value of responsibility in contracting; but each of some 400 persons in St. Louis now place that value at \$700.

Force Account Again

IS IT best to do public work by day labor? This question is asked in this issue and answered by three experienced engineers. It has frequently been asked and answered in the past. Indeed the question is perennial. Also the answers this time are no more likely to be accepted as final than have the same answers of years gone by. There is little prospect that the situation will change. So long as contractors prosper by doing public work just so long will engineers aspire to save this profit for the public. And so long as political interference exists in the management of public work so long also will engineers be dubious of the chances for its economic conduct by day labor. To reason thus in a circle gets the argument of contract versus day labor construction to no definite end. Argument anyway is futile. Any argument is futile which

starts from assumed conditions which the two sides do not agree on. The conditions essential to successful day labor construction as stated by Mr. Holleran in his article in this issue are in the main part asserted not to exist by Mr. Brown. It serves little purpose under such conditions to wrangle about force account and contract construction as a preferable policy for public work. As they stand the three articles in this issue present the situation about as fairly as can be.

Winter Work Costs Less

AS EXPERIENCE with winter construction increases its disciples multiply. Last week at a luncheon meeting of the New York Building Congress both architects and builders stood up and proclaimed the doctrine that not only was winter building practicable but that it cost less than construction in the normal building season of eight months of spring, summer and fall. Some of the evidence presented by the several speakers is given on another page. The winter reduction in prices and the winter increase in the output of workmen make an astounding record. Indeed one must be cautious in accepting the figures at face value. With winter construction universal the various influences which now tend to lower materials prices and to prompt efficiency of labor would be largely modified. It is the dearth of construction in winter which now makes workmen anxious to hold their jobs by high production and that induces the materials producer to cut prices so as to keep his product moving in the normally dull sales season. It also has to be observed that building work offers a greater possibility for winter operations than do public works and more exposed operations generally. But when all allowances are made the elimination of seasonal operations is bound to reduce the cost level of construction. The task is to convince the building public against all the influences of habit and tradition that there need to be no seasons in building. Records of actual operations in winter such as were presented at the Building Congress meeting will do more to accomplish this task than will volumes of general preachment on the evils of industrial waste. The time indeed has come when less talk and more facts are badly needed in the warfare against seasonal construction.

Timely Business Statistics

BUSINESS statistics are rapidly becoming of more than academic interest. There was a time when mass figures on production, consumption, costs and prices were accumulated only by the census office and published many years after their collection. They thus became merely historical references for the professional economist and were of value mainly in assisting him in telling what really happened in the past. Today such figures have a live interest to every forward looking business man, because he is training himself to use them in the study of the immediate past as some indi-

cation of the immediate future. This requires above all that such statistics should be complete and timely. Both of these qualities mark the new venture of the Department of Commerce, known as the "Commerce Yearbook" which has just been published and which is noted on p. 952 of this issue. The current issue covers 1922 and the first months of 1923 and a new edition covering all of the current year is promised for next spring. No one business man is going to be interested in all the statistics the government has here placed before him but every man can find a section which reports some basic data that should guide him in his business.

Tourist Highways Profitable

TOURIST service is given special consideration in highway development in Wisconsin. Blessed with a wealth of waters and woodland which attract the vacationist, the state has been alert to realize, if these profitable visitors are to come and spend money, that the ways of access must be easy and that in this era of the automobile these ways are the public roads. It has found that well-kept, well-marked roads develop tourists. Recently it has undertaken to determine the number, length of visit and expenditure of these motor tourists. From careful traffic counts it finds, according to J. T. Donaghey, engineer of maintenance, Wisconsin Highway Commission, that there are 7,000 cars in and out of the state each way every day from June 10 to September 10. The average stay in the state of these cars is 10.8 days and the average expenditure per car is \$11.72 daily. Without going into the calculations in detail, it is noted that Mr. Donaghey computes the season's expenditure in Wisconsin by out-of-state motor tourists to be \$100,000,000. He believes that citizens of the state touring by automobile for pleasure spend twice this sum. But keeping to the out-of-state vacation visitor, it is obvious that a hundred million dollar crop created largely by good roads has high significance to state highway officials. It at least offers a good rejoinder to the complaint often heard from the farmer that improved roads are being built for visitors to wear out. As Mr. Donaghey well says: "Even though the tourist traffic is wearing out our highways and causing large annual expenditures for both construction and maintenance it is leaving profits enough along its trail to repair and build the highways much more rapidly than it wears them out."

A Time for Action

IN 1917 A DEADLOCK between a joint committee of the New York City Board of Estimate and the State Public Service Commission on the one hand and the New York Central R.R. on the other was the climax of six years of negotiations looking toward an improvement of the freight line serving the west side of Manhattan Island. It was particularly unfortunate because it followed so closely upon the tentative agreement which had been reached in 1916, when the railroad and the Board of Estimate were co-operating in the study, by which the railroad was to bear all the expense of the grade separation and electrification in exchange for certain parcels of land needed for its enlarged facilities. The deadlock resulted from an attempt to alter this tentative agreement so that the

railroad would get the land under a lease revocable in twenty-five years. Naturally, the railroad company considered that it would not be justified in making the expenditure called for by the improved facilities with the possibility of the lease being canceled a few years after the work was completed, and so rejected the new proposal.

In October, 1917, in commenting on the action of the joint committee *Engineering News-Record* said editorially "In six years possibly the commission, having studied the matter from all angles . . . will make the headway the board did in 1916. . . . But no solution will ever come that is enough better than the 1916 plan to compensate for the delay."

Six years have passed and under the spur of a new law which requires the electrification of all railways in New York City, and with a judicial decision which guarantees the railroad its right-of-way, the New York Central has filed the new set of plans for a west side improvement noted in the news section this week. In its chief features this closely follows the 1916 arrangement, but takes advantage of the state grade-crossing law whereby the state and city will each pay 25 per cent of the cost of the grade-crossing separation. In its minor features, the plan is not so elaborate as the 1916 plan and, in view of the state of the city's finances and the need of keeping down unproductive expenditures by the railroads, it is superior to the earlier plan, though that plan could have been put through in 1917 for a considerably less sum.

Opposition to the plan will come from three classes of people; first, those who are opposed to any proposition which is put forward to continue a railroad along the west side of Manhattan Island; second, from those who think that such a railway line should be a joint one, open to all the railroad companies having terminals in New York, and, finally, from residents of the Riverside Drive section who think that the railroad should be entirely hidden from their sight. The first objection is obviously absurd. The west side line is vital to Manhattan Island. The second objection has some argument in its favor, but is almost impossible of attainment without years of litigation, and even then can just as well be put into effect after the new line is built as before if such an arrangement is found to be practicable. The last argument is, in our opinion, an unreasonable demand for the expenditure of large sums of money in the elimination of a condition which, when the railroad is electrified, will no longer be a serious detriment to the community. There is no reasonable excuse for asking the railroad company to add that much to the cost of delivering goods to Manhattan Island, for that is what such an expenditure must amount to, and if the city has money to spend for such purposes it might better spend it in creating new park spaces down on the East Side.

The estimated cost of the completed project under the 1916 was \$50,000,000. The estimated cost of this lesser project is \$70,000,000. That much has already been lost by delay. The loss through delay caused by the present method of surface operation in the warehouse district and from inadequate facilities is enormous and must continue until the new facilities are provided. Further delay is unnecessary and costly. All the arguments pro and con have already been accumulated in the voluminous minutes of hearings held in the six years previous to 1917. There seems to be little reason for repeating them; the time is one for action, not for words.

Getting Metering Across

CONTRARY to the generally held view among politicians, the people may want water meters. At least that is what the recent experience of Chicago's officials would go to show. In analyzing the political psychology of the water-waste situation in Chicago the Western Society of Engineers concluded that the word "metering" was one of the big stumbling blocks in getting meters installed, for always the politician asked what meter company wanted to make a sale. In consequence in none of their recommendations did the society refer to anything but "water-waste prevention" nor did any of the city officials in their appeals to the public stress anything but waste prevention and the equity of paying for a measured service. As a result it looks as though the politician's objections were pretty well answered. In the November bills sent out to certain wards which were supposed to be particularly opposed to meters a letter was enclosed explaining how a flat-rate bill of \$5.50 would pay for 88,000 gal., or 242 gal. per day, if billed on the measured-service basis. Prior to this a hurried educational campaign in these districts had been made, consisting of talks before improvement associations. By return mail requests began to come in by the hundred, so fast that the appropriation for meters bids fair to be soon exhausted. Aldermen usually know a good thing politically when they see it and unless all signs fail this response of their constituents is going to make them a bit careful about opposing a universal metering ordinance now under consideration. What the majority of the people want and what the aldermen give them will coincide if only the people have the means of letting their wishes be known.

Define Highway Research

CO-ORDINATION of thought is the first task of highway research engineers. Research now means too many things. One man is thinking of pure research to disclose fundamental scientific principles and another is thinking of investigation which discloses the adaptability of a local material for a local road building purpose. Another man confuses routine test analyses with objective investigation. Again one man is searching to find how he may determine and state precisely the problem to be solved and another is seeking the solution first by working all ways from some outcropping factor which has thrust itself into his immediate planning. At the American Research Council meeting two weeks ago of the Advisory Board on Highway Research each of these thoughts was in evidence at some point in the reports and discussions. The fact in no way justifies censure of the work so far of the Advisory Board. It has had a handful throughout its short life of two years in bringing the various highway research agencies into sufficient co-ordination of activities to prevent constant repetition and duplication of experiments. This it has done, perhaps not completely, but in a noteworthy measure. As a result we are now getting to have in America cumulative experimentation in highway and highway transport engineering. Perhaps co-ordination of research thought is harder to attain. The engineering bent of mind is less toward pure research in the sense that we speak of pure science and more toward determination of facts to be used in solving a specific detail in actual design or construction which occupies

immediate attention. There is the further obstacle that funds are not often plentiful for extended research merely to define and state a problem to be solved by further research. The engineer has a hard task to explain expenditures for research that cannot be immediately realized on in the way of usable data. But even accepting these conditions research thought can be made more precise and perhaps the task can well be begun by definition by the Advisory Board.

Co-operative Rail Study Begun

WHAT we have long believed to be the most promising plan for improving the quality of rails, to wit, co-operative study of rail troubles by mill men and railway engineers, has just been put into practice. A joint conference group of representatives of the two interests met at Washington recently, on invitation of the Bureau of Standards, and agreed to enter into such study. Railway and mill men have met before this, many times, but usually for the purpose of quarreling over rail specifications, which proved to be fruitless business; but the same parties that could not agree under those conditions will be able to reach a useful result when they are on the same side of the table.

For the present a single factor of unsatisfactory rail performance, the transverse-fissure type of failure, has been taken up for consideration. The first attack is through a statistical study of fissure breaks; this fact has just been announced by the American Railway Association in calling upon its member lines to compile and forward all pertinent data in their possession. In all probability this study will throw new light on the long-disputed question whether fissure failures exhibit furnace-heat influence or track-service influence more strongly. This question is necessarily the starting-point of discussion, as the difficulty of improving rails has been largely due to the opposition of view between those who hold that excessively severe track service causes fissures and those who hold that some elusive metallurgical defect is responsible. The recent contribution to the subject of James E. Howard has enlivened this opposition of view, the more so as railway engineers are accumulating strong evidence pointing toward the predominating influence of "sick" heats of steel upon fissure failures.

So long as opinion differed sharply on a fundamental point of this kind, the chance for writing better rail specifications was zero or negative. But the co-operative effort now begun—and let us hope it will not become prematurely deceased—is almost certain to develop enough definite knowledge to better this condition. It will serve a very direct need of modern railway engineering, moreover, if it succeeds in showing a way by which the new rails of very heavy section (above 100 lb. per yd.) can be given as high a carbon content as wear and strength demand, without introducing increased liability to fissure formation.

Perhaps even at this early stage of the work it may be serviceable to recall that where a question has two sides each defended by strong argument it is usually found that both sides are right. So in the present matter, the full data may show both excessive track service under certain conditions and defective steel in certain lots of metal. In that event the gain from the newly begun study will be only the greater, since it will have a beneficial reaction on both the railway and the steelmaking art.

Two Reinforced-Concrete Bridges in France

Vesubie River Arch Structure and Bowstring Bridge Over Maudit River at Nantes Are Typical Examples of Recent Long-Span Concrete Bridges

By W. L. SCOTT

Chief Engineer, Considere Constructions, Ltd.,
London, England

TWO BRIDGES of considerable span, one across the River Vesubie and one at Nantes, provide excellent examples of the progress of reinforced-concrete bridge construction in France. Both of these bridges have been constructed to Considere designs and while being similar in elevation, are entirely different in type. The former is an arch bridge, thrusting on mass concrete abutments, and the latter is a bowstring bridge in which the horizontal thrust given by the arched ribs is taken through the ties formed at deck level.

16½ ft. wide and two footpaths, one on either side, giving a total width between parapets of 24 ft. As will be seen from the illustration, the entire deck platform is suspended from the main arch ribs and with this arrangement no interruption is given to the river when it is in flood.

The temporary staging used in the construction of this work was of the ordinary type in which the weight of the structure was carried on transverse trestles, which carried longitudinal timber trusses, so braced that each vertical suspender was strutted to the transverse trestles.

Temporary Hinges Employed—There is no particular novelty in the design of this structure, with the possible exception of the type of temporary hinge employed. Fig. 2 illustrates this hinge, and the thrust being taken by it when the photograph was taken amounted to 400 tons. These temporary hinges are designed and placed so that they neutralize the bending

FIG. 1.—CONCRETE ARCH ACROSS VESUBIE RIVER

Deformation in the arch ribs of any bridge result from: (1) Compression due to the dead weight of the bridge and superimposed loading; (2) inevitable settlement of the abutments during construction and immediately after completion; (3) shrinkage of concrete during setting and hardening; and (4) atmospheric variations of temperature. It is essential that these factors be taken into consideration in the design of big span bridges, in which the main supporting members are of the arch type.

In the case of the bridge over the River Vesubie, the above factors are principally provided for by introducing temporary hinges at each of the springings and at the crown during construction, and, in addition, by completely severing the deck platform in a transverse direction near one end of the bridge.

In the case of the bowstring girder bridge at Nantes, concrete rocker bearings were provided at one end of the bridge and roller bearings at the opposite end thereby permitting angular as well as longitudinal displacement. It will be appreciated that temperature and shrinkage stresses do not require to be taken into account in the design, since the horizontal ties are affected in a similar manner to the arch ribs and approximately to the same extent.

Vesubie Bridge—The bridge over the River Vesubie (Fig. 1) is 344½ ft. long and with a clear span of 315 ft. is among the largest of its type in the world. The deck platform accommodates a roadway

FIG. 2.—TEMPORARY HINGE TAKES 400-TON THRUST; VESUBIE RIVER BRIDGE

Hinge is designed to neutralize bending moments due to shrinkage, shortening under load and abutment settlement.

FIG. 3—BOWSTRING GIRDER SPAN AT NANTES

moments due to shrinkage and arch shortening under load, in addition to any elastic settlement of the abutments.

Experience has shown that the stresses due to these latter effects frequently exceed the maximum calculated stresses due to the ordinary arch thrust and moments due to superimposed loading and temperature variations. It would be quite impossible satisfactorily to erect a bridge of this type and span if the flattening of the arches resultant from the above effects were, as is so often the case, ignored.

A certain amount of criticism has been advanced against temporary hinges, to the effect that these cannot properly be regarded as hinges, owing to the resistance given by the main tension reinforcement in the ribs being present and effective in preventing the required distortion. However, such hinges are always designed so as to be sufficiently ductile to compress under load in such a manner that little, if any, tension is ever brought upon the exposed main reinforcement of the rib member. Moreover, the curved main reinforcement is always exposed for a length sufficient to enable it to deform to the very small extent required without distress.

Wind Pressure.—The Vesubie bridge is situated in a very exposed position and the question of lateral wind pressure had to be taken into careful consideration. A pressure of 50 lb. per square foot was the figure adopted in the calculations, and this was wholly taken for the central portion of this bridge by the curved ribs, which were suitably provided with lattice bracing so as to enable them to work as a horizontal curved girder. Near both ends of the bridge a heavy frame has been introduced and this transmits the lateral forces to the deck platform, which in turn transmits the total lateral thrust to the abutments in cantilever fashion.

Immediately after completion the bridge was tested by vehicles aggregating 100 tons in weight with a resultant maximum elastic deflection of $\frac{3}{4}$ in. The bridge has now been open to traffic for about a year and a recent examination of the structure has shown that there are no cracks of any kind in any part of it. In view of this the bridge can be classed as a truly elastic structure and the various assumptions made in the design of the work thereby justified.

Maudit River Bridge.—This bridge, at Nantes, beyond the fact that the deck platform is suspended from the arched ribs, requires entirely different treatment

in design from the Vesubie bridge, as a brief consideration of the differences in supporting conditions will make clear. The span of the structure in question is 180 ft. and the rise to the arch ribs one-sixth of this amount, which proved to be the economical ratio. (Fig. 3).

The principal advantages of this type of bridge are clear waterway and simplicity of abutment supports, while a disadvantage may be stated to be the limitations of this type of structure to bridges of reasonably narrow width.

Vertical Suspenders.—In the case of the Nantes bridge, the footpaths have been cantilevered. With such an arrangement the bowstring girders can be employed for most cases ordinarily met with. Particular regard has been paid to the design of the vertical suspenders, which are made flexible in the plane of the girder so that they do not offer appreciable resistance to the elastic deflection of the curved ribs. These members also require to be made sufficiently rigid in the

FIG. 4—SECTIONS OF THE AT SPRINGING AND CROWN, MAUDIT RIVER BRIDGE AT NANTES

transverse direction, so as to transmit the lateral force of the wind coming upon the girders to the deck platform, which acts as a horizontal girder in transmitting the total lateral thrust from the wind to the shore supports.

Until quite recently, some engineers have rigorously opposed the employment of such reinforced-concrete members subjected to pure tension, particularly where these are placed on the inner edge of the pavement, in which position they may be subjected to serious damage from vehicles becoming out of control, but the soundness of design and stability of the structure are borne out by the fact that two or three ties have, at times, been entirely destroyed without any apparent effect on the deck platform.

The curved ribs for the bridge at Nantes are of "I"-section with the upper and lower ribs heavily spiralled. In the design of bowstring girders, the most important point requiring consideration is the connection between the curved ribs and the horizontal ties. It will be appreciated that the entire horizontal thrust from the ribs has to be absorbed into the ties over a relatively short distance and in order that this shall be done satisfactorily, the varying intensities of stress at these connections have been carefully studied and a design formulated whereby these connections can be given the same reserve of strength as obtains in the

remainder of the bridge with the minimum quantities of concrete and reinforcement.

Arch Centering—The temporary staging for the Nantes bridge was built as follows:

An arch truss constructed in two halves was erected and supported on a temporary bracket built on the abutment walls. Suspended from this truss by rods was a horizontal platform at the level of the underside of the horizontal tie. This truss was designed to carry the weight of half of the curved rib and one-half of the horizontal tie. These portions of the girders were then concreted and allowed to take their initial set, after which they were capable of carrying their own weight and the additional weight of the remaining concrete necessary to complete the girder when green. With the girders in position, the deck platform was constructed, the staging for this being supported on the girders themselves.

By this method, the relatively high cost of centering is obviated and the structure is rendered advantageous both from the accommodation and economical standpoints.

Engineering—Profession or Business?

By C. R. YOUNG

Assistant Professor of Structural Engineering,
University of Toronto, Toronto, Ont.

*Extracts from inaugural address as chairman, Toronto
Branch, Engineering Institute of Canada.*

THERE is perhaps no question more frequently asked than the time-worn one as to whether engineering is really a profession or not. It has been the ideal of many leading engineers to place engineering on a purely professional basis and to divest it of the characteristics of a business which it has taken on in recent years. One must frankly admit that the results achieved have not been gratifying and that engineering is, if anything, further from the status of a pure profession than it was a generation ago.

If one were asked to define the essentials of a profession, one might say that properly the professional man should make his services available to such clients as care to consult him, and generally for stipulated fees rather than for a salary. Relations with the client should be on the highest possible ethical basis and no measures should be adopted for the securing of commissions which would not be acceptable in type to those prevailing in the professions of law and medicine. One might enumerate as some specific essentials of an engineering profession, the possession of skill and learning by the practitioner, the maintenance of high ethical relations with the client, and the observance of altruistic motives in his relations with the public.

So basic is the idea of learning in a true profession that one often hears mention of the "learned professions." It is inadmissible for the engineering practitioner to be an ignorant or unlettered man. Although the proprietor of a barber shop or of a shoe shining stand may be operating for the benefit of such customers as may care to patronize him, and for a fixed fee, it cannot be maintained that these callings are in the category of professions, in spite of the recent effort to incorporate barbering in British Columbia as a skilled profession. But on the basis of learning as a requisite, however, one might very properly include in the ranks of the "learned professions," the work of the skilled accountant or auditor, who in his field maintains toward clients relations that are comparable with those maintained by the professional engineer.

A basic essential of professional life is that the relations of the professional man to his client should be those of the most exalted trust and of the most circumspect solicitude for the interests of his employer. Telford, for example, while acting as an engineer for several canal companies declined an appointment as engineer to the Liverpool & Manchester Ry., on the ground that it would prejudicially

affect the interests of his existing employers. Sir John Fowler was pre-eminently a shareholder's engineer. He restrained his natural impulse to create great and enduring works for monumental purposes and made sure that the interests of the persons who were furnishing the money were primarily observed. The public very properly expects of a professional man a high attitude with regard to public obligations. It expects him not only to further the interests of the people at large, but to prepare himself for the better performance of such service. The appropriate attitude to his profession might very well be put in the words of Francis Bacon, "I hold every man a debtor to his profession; from the which as men of course do seek to receive countenance and profit, so ought they of duty to endeavor themselves by way of amends to be a help and ornament thereto."

Smeaton's attitude in this regard would have fully satisfied Bacon. He held that "the abilities of the individual were a debt due to the common stock of public well-being." Having this in mind, he limited his professional employment so that he might devote a certain portion of his time to self-improvement and scientific investigation. He systematically resisted tempting offers to attract him from this settled course.

One must admit that the present status of engineering is that of part profession and part business. The methods of solicitation of new work in engineering are by no means in conformity with those observed by the leaders in the professions of law and medicine. Intensive canvassing and lobbying which characterize the conduct of some engineers in the consulting field at the present time do not well comport with the high ethics of Smeaton and Telford. They are of one and the same type as the methods employed to secure orders for bacon or boots.

The competition that is sometimes introduced by engineers with others who have to all intents and purposes secured a given piece of work is not that characteristic of a pure profession. Thus, when the plans of an engineer have been accepted and tenders are called thereupon, it may be questioned as to whether alternative designs are properly tolerable without the full prior knowledge and consent of the client's engineer. It is, of course, a common procedure for engineering contractors to submit their own designs in competition with those of the engineer in charge of the work, and the practice is so firmly established that it is not likely to be given up. In essence it is an embarrassing procedure. It in effect proclaims that the client's engineer has insufficiently studied the situation and that he has overlooked the merits of another scheme which might prove cheaper than the one which he recommended. Anything which lessens the confidence of the client in his engineer's complete mastery of the subject may well be considered as questionable ethically, but so far have we proceeded from pure ethics in the practice of engineering that this procedure often excites no comment.

Under such conditions it becomes very difficult to frame a comprehensive code of ethics for engineers. When they are operating in part as professional men and in part as men of business it does not seem practicable to establish a purely professional code of ethics that will procure uniform observance by the engineers of the country.

New Large Bridge for England

The Great Western Ry. of England has offered to meet half the cost of a great bridge which it is proposed to build across the Severn and the Wye Rivers at Beachley. The offer is made in conjunction with a tentative estimate that the structure will cost \$11,000,000. As the bridge is to be used for vehicular as well as rail traffic, the Ministry of Transport and the local authorities are expected to pay the other half of the cost. The increasing volume of rail traffic between England and South Wales has reached such a point that the tunnel under the Severn is inadequate. The bridge scheme is opposed by the city of Bristol on the ground that it will interfere with navigation.

Through the Reclamation Country

By F. E. Schmitt

Associate Editor, *Engineering News-Record*

THIS is the tenth of the series of letters written by Mr. Schmitt during a journey recently made through the West in which he visited irrigation projects, studied developments, and interviewed builders, operators and settlers, in order to present to our readers the actualities of reclamation as revealed to an unprejudiced investigator.

The series of letters began in the issue of October 4.

El Paso

STATE and local responsibilities toward reclamation force themselves on one's notice chiefly because they are wholly ignored; but nearly every phase of project operation contains some reminder of them.

The federal reclamation enterprise seems to be of little interest to the individual states out here. The states were active in getting appropriations for money to be spent on projects within their own boundaries, but then seem to have lost interest. They are and have been wholly apathetic toward the agricultural communities which the nation has worked hard to establish in their midst. They do nothing to assist these communities in working out their troubles, except for the small item of running experiment or demonstration farms on the projects, usually in co-operation with the federal Department of Agriculture, which began the work. In fact, occasionally a state is directly hostile to reclamation, or at least works against its interests, as the state of Washington, whose speculation in school-land prices delayed the development of these lands for years.

State Indifference.—One might think that when the national government builds within a state large public-service works which will greatly increase the state's productive wealth and human resource, it would be the state's most interested care to assure the success of the communities served by these works, through helping them develop. But this opportunity and responsibility do not seem to have penetrated to the legislative mind in the state capitals, or, for that matter, to the public consciousness in the West. As suggested in an earlier letter, the attitude toward the federal projects is that they are Uncle Sam's business, and nobody is going to take care of it for him. The great white father in Washington carrying the helpless reclamation farmer in his awkward bureaucratic arms, and hobbled with red tape, may flounder and stumble as much as he pleases, the state will not lift a hand to help. Why?

More personally than the state, the reclamation community itself is concerned in its own success—the community, rather than the individual farmers. Every merchant or banker in the project town is directly touched in his pocket-book by the success or the failure of the smallest farmer on the project; and so long as this farmer's production is held down by lack of proper farming knowledge or lack of money the merchant and the banker, too, will not prosper as fully as they might. The neighboring farmer, too, is affected, for he will have better markets, better transportation facilities and schools, and better human contacts, if all his fellow settlers are doing well. Thus, the whole community, as a unit, has most to gain (or to lose) by proper

promotion (or its neglect)—by agricultural stimulation, live-stock development, creation of marketing, and other co-operative facilities, provision of means for financing, in short all the kinds of work involved in rapid upbuilding of the region. But the community, like the state, has done virtually nothing.

Beginnings of Community Effort.—With one or two exceptions, the water users' associations, which deal primarily with contract relations between farmers and government, have done no development work at all. To note an exception: Just north of here, at Las Cruces, New Mexico, headquarters of the upper part of the Rio Grande project, the Elephant Butte Irrigation District is going into promotional work with a good bit of zest, and its office, proudly named "Temple of Agriculture," is meant to become the real agricultural headquarters of the valley. If the district keeps up this purpose it will bring the farmers big dividends. Reclamation farmers generally have vaguely expected the Service to do the boosting and nursing for them; once they learn that the Service cannot do this, or will not, and that they themselves are by all odds the best people to do it, the present problems of reclamation will be pretty well out of the way.

And like Elephant Butte, one or two other associations have begun to proceed more aggressively. Progress is making. If it continues, it will in time arouse state governments to an understanding of their duty.

Another development on this Rio Grande project attracts attention: the Gateway Club here in El Paso, a colonization promoting society organized by local business men, which aims to get desirable settlers for the unfarmed lands of the project. Unless this movement stops short of its best possibilities, it is bound to go on into agricultural and financial development work, and so may become a permanent model for the type of organized activity that every project needs. This El Paso development is specially interesting because the city has been slow to wake up to its place in the scheme of reclamation. One reason why the Rio Grande project did not develop any faster than others, though favored by having a large and rich city in its center, is that El Paso at the start took no more interest in the creation of the new agricultural region around it than it would in the addition of a wing to the local post office. Cattle business and other preoccupations were more important—until now, when other interests have slackened off, agricultural production is the thing that puts jam on the city's bread. Today the business men admit that they were wrong, and that well directed promotion work in the earlier years would have meant greater advance for city man as well as farmer.

Water Users Will Not Operate.—Local responsibilities are not only slow to be perceived, but even when perceived they seem to be uncomfortable. On nearly all the projects, the water users will not operate their distribution systems. They complain about government operation, and say they could do the work more cheaply; but they won't. That they are able to operate, and operate well, is shown by experience in the three places where the water users are operating: a section of the Strawberry Valley project (Utah), the north side of the Minidoka project (Idaho), and the Salt River project (Arizona). Still the farmers on the other projects are unwilling to take over the work and relieve the government of a function that does not belong to it.

that it never intended to assume, and that was forced on the Service as an unavoidable necessity.

The motives of this unwillingness appear to be a little mixed. The president of a water users' association told me that government operation assures fairness, and he seemed to apprehend politics or other discrimination if the users operated. Several farmers feared the chance of emergency happenings rather than the risk of unfairness. Another man made it evident that he felt it was to the landholders' interest to have the government hold the bag as long as possible. Grounds for any of these views can not be found. If the users took over operation on all the projects, with only such governmental supervision as would protect the equities, more than half the causes of discord between government and farmer would be eliminated.

Reasons For Local Action—Local action has many advantages, among others the ability to deal more fittingly with local questions and with the requests and complaints of individual farmers. Farmer boards, where they are in action, are much more severely impartial than the Reclamation Service people, in spite of the fact that one of the standing charges against the Service is its lack of human feeling. On one project, where relief applications (under last year's Congressional act authorizing deferment of water charges) were referred to the water users' board, this board turned down many more than the Reclamation Service. In another case, claims of many kinds (for rights-of-way, damages, and the like) were passed on by the water users, and their attitude was quite flint-hearted, whereas the Service usually has to go easy rather than hold the individual to strict justice. Dealing with these matters of human relationship is so naturally in the sphere of the local community, made up of neighbors and fellow farmers—a mutual court, as it were—and is so far from being the proper function of the Service, that one wonders why the local people have insisted on sitting back so long.

In discussing how and by whom the vital work of colonizing and developing a reclamation project is to be carried out, a Western engineer said very aptly, "It is impossible to have a strong development policy nationally administered." Settlement and cultivation must be directed from nearer at hand. Except for two factors, it would best be dealt with by the local people themselves, in the opinion of the best informed men out here. These factors are (1) the need for financial strength to support the initial financing of the settlers, and (2) the desirability of adequate breadth of view and adequate resources back of the movement to guarantee progressive development and maintain the value of the enterprise. Half a dozen settlers on a newly opened project are not a sufficiently large community to do any development work except in their own half-dozen backyards; and, as a former irrigation manager said, "The irrigation district system is not applicable to the reclamation of raw desert. Every successful district that we have was preceded by some other attempt at irrigation."

Greater Productivity Needed—Breadth of view and sufficient resources of men and property are required also as a protection against various mischances of development. Irrigation farming, because it is expensive, must be operated for high productivity, and this productivity must be maintained. The present condi-

tion (on the authority of agricultural observers on the projects) is that the reclamation projects in particular and irrigation farming in general are not producing as much per acre as they should, by a large margin. It may suit the individual farmer to raise less than half a bale of cotton per acre, but it may be all wrong from the standpoint of the project and of the state. Every sugar company that contracts with farmers for raising beets maintains a skilled corps of field agents who go around among the farmers constantly to help them raise beets the right way and raise enough per acre, and to see that they do so; the companies need high beet production and high sugar content, and know that they will not get it unless they make sure that they get it. There is plenty of opportunity for similar encouragement and agricultural aid to higher productivity on the reclamation projects generally, but the Reclamation Service is not permitted to use its money for such aid work, and the Department of Agriculture does only the little that it can get funds for, which is not much. Besides, some farmers prefer to make a failure their own way rather than a success by advice.

In addition, the danger of decrease in producing power of the soil has to be looked out for, and when necessary fought by whatever means may be required. Some of the irrigation lands are showing signs of decreasing productive power of the ground; and whether this is due to accumulation of salt in the soil from faulty irrigation, or to lack of manuring, or to other causes, it must be studied and combated—which again will usually require a broader view and a more resourceful authority than the local community itself. In fact, the continuing partnership between farmer (or community) and state (or federal government) is a central point of the irrigation business.

To take another aspect of the case, in one of the oldest irrigation states, Utah, fully a fourth of the million and a quarter irrigated acreage has gone out of production through seep, plainly the result of neglect on the part of both individual farmer and local community; this is not reclamation-project land, of course. It is immensely against the interest of the state of Utah (though Utah apparently doesn't know this) to permit the local people to let good agricultural land to go to ruin in this way. The state should have stopped the damage in its early stages, and in any event should take the lead in remedying it. But it failed to do the one, and is not now doing the other. Yet Utah is now angling for many millions of dollars of Reclamation money to put more land under cultivation.

Value of Co-operation—Productivity is only one of several objectives in bettering irrigation and reclamation performance. The right kind of co-operative effort on the part of the local community, the state, and the national government could realize these objectives and at the same time guarantee the equities of the enterprise, but such co-operation does not now exist. The big fighting point of money troubles between reclamation settlers and the Service is closely tied up with productivity. A California man, engaged in orcharding, said that he didn't care how much the water cost, as it was all a question of how much he could get out of his land. An Arizona man emphasized the desirability of higher production on his project by quoting a business epigram, "To hell with the expense account so long as we get the business." In contrast, when

one project is found to be running virtually as a single-crop project, 80 per cent of its production being alfalfa, one is not surprised this project has money troubles.

On that particular project, community action to bring about higher grade farming, chiefly by diversification of crops and planting of high-value specialty crops, has at last gotten a start. In the same way, another project that has had serious money troubles has within the last year developed some energetic community action toward increasing the amount of dairying; bankers and business men in the town have organized for the purchase of high-grade dairy cattle in order to stimulate dairy farming. All such local efforts may in time do away with light-weight farming, planned to give the farmer plenty of time for automobile touring in the best season, much of which is found on some of the projects. "Agricultural aid and enforcing the farmer's financial responsibility are necessary," as one man put it, who in the combined position of farmer, banker and water users' official has wrestled with the project-farmer problem in many campaigns.

Although the states have not taken up their share of the reclamation project burden, they have interested themselves actively in irrigation along another line, within the past few years. They are trying to make irrigation securities attractive to private investors by various devices which purport to give state backing to private irrigation. This matter, however, ties up closely with other aspects of future irrigation and reclamation developments.

Self-Supporting Reinforcement for Concrete Floor

**I-Beams With Flanges Slit and Bent to Provide
Integral Shear Members Carry Steel
Forms—Rods and Wire Mesh**

A SELF-SUPPORTING steel reinforcement composed of special I-beams in a framing which also serves to carry steel formwork of special design and thus minimizes the amount of falsework, is a structural feature of the reinforced-concrete floor framing in the Sir Walter Hotel, built recently at Raleigh, N. C. A typical panel is shown in Fig. 1, and a typical floor section in Fig. 2.

In this new type of floor framing, the reinforcement of girders and joists consists of steel I-beams which have the top flanges sheared or slit and the resulting

FIG. 1—I-BEAMS WITH INTEGRAL SHEAR MEMBERS FORM REINFORCEMENT FOR CONCRETE

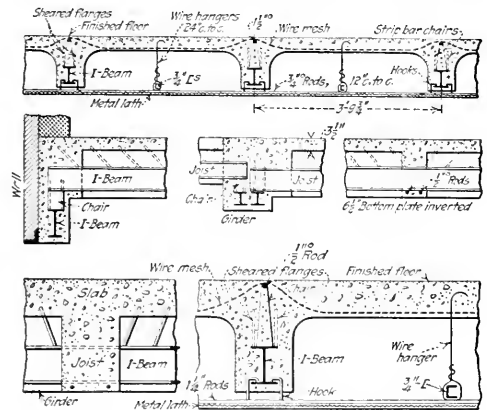

FIG. 2—FLOOR CONSTRUCTION OF SIR WALTER HOTEL

strips bent upward so as to form rigidly connected diagonals or shear members extending into the concrete of the upper part of the girders and joists and into the floor slabs. Where the sheared I-beams rest on similar beams they are fastened together by clips over the flanges. Where the beams pass above supporting I-beams they are bolted to chairs which rest on the lower beams and are clipped to their top flanges. Butt joints in lines of sheared I-beams, such as in joists over girders and in girders over columns, are spliced in the web by flat plates and bolts.

Additional reinforcement is provided in some cases by rib bars bent in the usual way, the bars resting on small blocks or separators on the lower flanges of the I-beams and having their ends bent so as to lie in the concrete slab. Wire mesh laid in the floor slab is raised to the top over the joists, where it is held by 1-in. rods and the diagonal strips of the I-beam flanges. For convenience of transportation, the I-beams are shipped with the shear members raised only slightly above the flanges, as shown in Fig. 3. A special tool is used on the work to raise these members to a uniform angle of 45 deg.

Hooks attached to the bottom flanges of the I-beams carry flat steel forms with edges turned up to catch the hook on a Z-section plate. The lower lip of the Z-plate carries the lower edge of a steel form of inverted trough section. These forms are removed after the concrete has set, so that they can be used several times. The hooks remain permanently and serve to carry rods to which is wired the expanded metal for a suspended ceiling beneath the joists. To prevent sag of the rods they are attached to a 1-in. channel placed midway between the joists and supported by a hanger wire attached to the steel mesh embedded in the concrete floor slab.

The steel beams are strong enough to carry the dead load of the floor. It is stated that this high carrying capacity not only gives added strength to the reinforced-concrete structure, but also enables the slab forms to be removed in a comparatively short time, thus saving expense and time in erection. Further, since the I-beam framing supports the forms, it can be erected for two or three floors at a time. In the Sir Walter Hotel this type of construction is said to have permitted the use of longer floor spans (35 ft. 2 in.) than

would have been practicable with ordinary reinforced concrete construction, so that one row of interior columns was eliminated and the cost of the building reduced correspondingly.

This type of framing is claimed to combine essential advantages of both reinforced concrete and structural steel construction. It has the former's economy in steel and the latter's self-supporting property, while it eliminates much of the expense and inconvenience of formwork for concrete and the weight and expense of structural steel construction. As a rule the only tim-

Moving Platforms, an Untried Form of Rapid Transit

Large Capacity at Low Operating Costs—Simple Equipment—Eliminates Congestion—Low Train Resistance

A PRACTICAL demonstration of a much-discussed method of rapid transit, the moving platform, is now being made in Jersey City, N. J. This demonstration section is made up of a loop 200 ft. long and 100 ft. wide in its outside dimensions, consisting of three continuous parallel platform loops, operating at 3, 6, and 9 m.p.h., respectively, and one inner stationary loop. Each platform is about 1 in. higher than the adjoining inner platform and overlaps it sufficiently to afford protection on the curve. Each of the moving platforms is made up of a series of small trucks 8 ft. long with circular ends, exactly fitting into each other. These trucks are supported at one end by two independent wheels with ball bearings and connected at the other end to the preceding truck by a universal coupling. The fixed platform and the two inner slow moving platforms are about 30 in. wide and have no seats as they are intended primarily for people getting on and off the fast moving platform, which is about 60 in. wide and provided with two-passenger seats at 32 in. intervals. Most of the platforms are floored with wood, but there are a few sections floored with such material as diamond safety tread and compressed sheet metal covered with anti-slip mastic.

Tests of this equipment made by the Electrical Testing Laboratories of New York on a track section consisting of 73 per cent curves indicate that such a three-stage moving platform would require 150 hp. per mile to operate it. This figure should be considerably less on sections of straight track.

Two methods of propulsion are used for demonstration purposes. The 3- and 6-mile platforms are driven by racks and pinions, the racks mounted on the underside of the platform as independent sections for operation around the curves, but so set that they form a continuous rack when passing over the motor-driven pinions placed on the tangents. The pinions would be spaced from 1,000 to 1,500 ft. apart on large installations. The 9-mile platform is propelled by elements of an induction motor, the secondary or rotating element,

FIG. 3—I-BEAMS AND FORMS IN PLACE FOR GIRDER, JOIST AND SLAB

ber support for the forms consists of a post at the mid-span of each beam, or two posts in spans of over 32 ft. In this way the usual forest of timber falsework is eliminated and the floor space is largely available for storing materials and carrying on the work of the various building trades.

The Sir Walter Hotel is a ten-story structure, 105 x 140 ft. in plan, of reinforced concrete throughout and having a brick and stone facing. The typical floor panels are about 17 x 18 ft. with joists spaced alternately 4 ft. and 5 ft. c. to c. For the shorter spans there are 4-in. I-beams topped with 6 in. of concrete including a 2½-in. floor slab. For longer spans there are 8-in. I-beams with 10-in. concrete including a 2½-in. slab. Live-loads for floors are 100 and 150 lb. on the first floor, 100 lb. for the second, and 50 lb. for all upper floors.

This new floor system with sheared I-beams was designed by the Truscon Steel Co., Youngstown, Ohio, and was built by the C. V. York Construction Co., which had the general contract for the Sir Walter Hotel. The architect was James Salter, Raleigh, N. C.

Agitate Tennessee-Tombigbee Canal

Interests at Mobile, Ala., are agitating a connection between the Tennessee and Tombigbee Rivers. While their headwaters are separated by only 25 miles, a lock canal would be necessary to carry the waterway over a range of hills. As the waterway would parallel the Mississippi River, some difficulty may be experienced in financing so expensive a development.

FIG. 1—THREE MOVING PLATFORMS SHOWING ARRANGEMENT OF TRUCKS

made in straight 8-ft. sections clamped to the underside of the cars, forms a continuous secondary, and the stationary or primary element of the motor is made in sections 5 ft. long placed between the rails in groups about 140 ft. apart, with an air gap of $\frac{3}{8}$ in. between the primary and secondary elements. The motor elements are supplied with three-phase alternating current with a frequency of 37½ cycles per second. If the 3- and 6-mile platforms were driven by the same means, the frequency would be reduced to 12½ and 25 cycles respectively.

From the point of view of maintenance, this arrangement has the advantage of few moving parts to get out of order, no concentrated loads or high wear, and few

means of the slow-moving platforms. The rolling stock weighs 350 lb. per seated passenger as compared with 1,500 lb. in subway trains. Another advantage claimed for the moving platform as against subway is that as it only requires a clear space 12 ft. wide and 9 ft. high for a platform moving in one direction such a platform system could be put in the space now occupied by sidewalk vaults in city streets. Such a system could have entrances or exits at any convenient points; either directly into the buildings or by stairways to the streets, as it is possible for people to leave the fast moving platform at any point by means of the two slower moving platforms. Another advantage claimed for this type of transit is that should the main fast

FIG. 2—DEMONSTRATION PLANT OF MOVING PLATFORM SYSTEM
Showing inner fixed platform, two narrow slow moving platforms, and wide fast moving platform on the outside.

expensive parts. It also has the advantage that as the traction is not developed through contact of the wheels upon the rails, the rails can be kept greased to reduce friction on curves. In the matter of power consumption, such a system has an advantage over independent train units in that there is no power lost in stopping and starting, the platform being always in motion with the passengers walking on and off at the stations by

moving platform be disabled, the two slower moving platforms would still be in operation, and it would be possible for people to use them at the slower speed, and also that in case of some very unusual accident stopping all three platforms, they still would present a well lighted walk, which the people could use to the nearest exit or to continue their journey on foot.

In the matter of passenger capacity, the seated capacity of the 9-mile an hour platform is 35,640 passengers per hour, which is 50 per cent in excess of the seated capacity of the combined local and express services of the New York subways. With the standing room occupied on the fast platform, this capacity can be more than doubled. In addition, at the times of peak loads, passengers could also use the 6-mile an hour platform. As the platforms are always in motion, there should be no crowding at the loading platforms, as people can walk on as fast as they reach the moving platforms.

FIG. 3—SECTION OF HIGH SPEED PLATFORMS SHOWING ONE METHOD OF PROVISION

Showing the secondary or rotating element of the induction motor on the underside of the car body and the primary element in its fixed position between rails.

U. S. Urged to Improve Flushing Creek

The Board of Engineers for Rivers and Harbors is being importuned by interests in the Queens area of New York City to improve Flushing Creek with the idea of providing industrial sites along its course with 12 ft. of water. It has been pointed out to the board that the development of the Queens area is proceeding at a very rapid rate and that the development proposed would insure the erection of plants in what now is an undeveloped area. The board has expressed no opinion in this particular case, but its general policy is to develop the mouth of such a waterway and leave the development from that point on to local interests. An example of that policy is the Buffalo River.

Federal Land Reclamation: A National Problem

7. Financial Troubles of the Reclamation Farmer and How They May Be Relieved

By JAMES T. WHITEHEAD

*President of the North Platte Valley Water Users' Association.
and President of the Mitchell State Bank, Mitchell, Neb.*

*The Seventh of a Series of Articles on the History
and Performance of the Great Government Adventure
in Irrigation of the Arid Lands of the West.*

RECLAMATION of arid lands by the national government is a success so far as the engineering features are concerned. There have been no failures of reservoirs to hold water, canals to carry water, nor dams to divert it into reservoirs or canals, except possibly in very unimportant cases. The increased production of foodstuff and the increased demand for manufactured goods is unquestioned. But there are two features of the problem, other than that of engineering, that are of vast importance and it may be seriously questioned whether as regards these a success has been achieved. They are, *first*, the making of happy and prosperous homes, and *second*, return of the money advanced by the government. The solution of the second of these problems depends on the solution of the first, for the water users will pay the government as fast as they can, and the more prosperous they are the sooner will the fund advanced be returned. Under such conditions the whole matter rests on the question of making prosperous homes on the various projects.

When the Reclamation Act was passed no provision was made for any kind of selection of landowners or entrymen. The only requirement was, in the case of privately owned lands, any kind of a deal that looked to the original owner like a chance to get the purchase price from the buyer, and in the case of entrymen on government lands, a \$14 filing fee for the right to a homestead. The result was that the projects were settled by people of all kinds of ability, some good, some average, and others very indifferent. Under such a scheme of settlement it was inevitable that a considerable number of the settlers would not be sufficiently successful to keep themselves out of debt and make the required payments out of their farming operations, their only source of income.

Lack of Initial Capital—To operate a farm under irrigation requires a considerable amount of capital, which the entryman was not required to have and which in many cases he did not have. Any business that is under-capitalized is seriously handicapped; and this is as true of the farming business as of any other. To get sufficient capital to operate at all, the entryman had to borrow, and as he usually had only an entry on land whose title remained in the government he was obliged to borrow on short time and at a high rate of interest, giving such chattel security as he had. Generally this security included the prospective crop. The land being unimproved, it was necessary that the entryman build himself a house in which to live, the barn and other buildings, as well as put the land in shape to raise a crop. Debts were sure to accumulate which it would be difficult to meet.

Generally the land does not produce well enough to pay until the soil is built up by the application of barnyard fertilizer or by the introduction of some legume crop that will add to its fertility. This takes time.

When prices for farm products were at the peak and the payments to the government were low, the payments were for the most part made, but unfortunately the slump in farm prices came about the time the payments to the government had reached a high rate per acre, and delinquencies began to accumulate together with the penalties for non-payment. The penalty for failure to pay when due is one per cent per month. With payments due on money borrowed at a high rate of interest, with water payments to be made, under heavy penalties for failure to make them, the land seeded to alfalfa was plowed up and planted to crops which it was hoped would produce enough to meet payments required without regard to the building up of the soil for future crops.

As a result, the crops raised even on the good land were raised at a loss, and the farm was less fertile for the next year's crops. Depletion of the soil fertility was the result of endeavoring to make payments that could not be made from the crops raised, if due regard was given to the future prosperity of the farmer. The payments to the government and payments to other creditors could not be made and of course were not made. But for the ever-present hopefulness of the average farmer, the outlook would be discouraging, and it is not encouraging to any but the most courageous.

Deflation Effects—Agriculturalists have passed (or are passing) through one of the most depressing times in their experience. So much has been said about the deflation of the farmer that it is not necessary to repeat it, except to say that it was real and effective. Everything he had was deflated, except what he owed. Farm labor continues to be high-priced and inefficient, the cost of farm machinery is at the highest point, and the things that the farmer has to buy are at peak prices. This is a condition that all farmers generally have had to meet in all parts of the country, where irrigation is practiced as well as where it is not—in Iowa and in Idaho, in Michigan and in Missouri.

With prices of farm products far out of line with the prices of other things for so long a time, agriculture has been and is hard pressed. The farmers on government projects have had to meet all the discouraging conditions that have seemed so difficult to farmers generally where irrigation is not practiced, and in addition have been expected not only to take care of the obligations that are incident to farming, as all must do, but in addition to make cash payments to the government besides. This they could not do, and so came the demand that some respite be given them until it is humanly possible to make these payments.

Business Management the Way Out—Is the future of these projects hopeless? Has it been a mistake for the government to build these great irrigation works? One has only to travel over many of them with his eyes

open and see the crops raised in such abundance to be convinced that there must be a way of managing these projects so that they will succeed and the settlers on them become happy and be prosperous home owners and good citizens—real men and women, fathers and mothers of a future generation who will carry on the work of making greater a nation already great.

And what is the way? The same intelligent management, under the direction of men who are competent to manage intelligently, that is practiced by any successful corporation or business of equal size and importance. The Secretary of the Interior is the head of all the reclamation work being done by the government. He is the president and general manager of the corporation, so to speak. If failure results he must take the responsibility. Should he be held responsible and should he take the blame for failure if he does not have the authority to put business methods into practice, as has any other general manager?

But the general manager of a corporation works under the direction of and in conjunction with a board of directors. The board of directors is or should be composed of a limited number of men familiar with and interested in the success of the business. When it is found that some change must be made in the operation of the plant, the general manager can get his board together and the change can be discussed with the single thought of improving the plant or its operation. In the case of the government reclamation projects, Congress seems to be the board of directors. And what a board! More than five hundred members, scattered all over the United States, and composed for the most part of men not at all interested in the working of the plant and with little or no knowledge of its needs or requirements! But the board cannot be changed. It is the Congress and it must continue to be the Congress. Under such management the wisest possible discretion must be given the general manager, and he must be trusted to deal with the problems as he sees they must be dealt with and take the responsibility of making a success of the venture. This authority he does not have under the present laws.

Give The Secretary Power—He can, under the law as it now is, build a project and operate it practically as long as he likes, without requiring any payment to the government for the cost of the project, so long as he does not issue a formal order to commence paying. The formal order to commence paying, called Public Notice, announces the date payments shall commence and the total amount that must be repaid to cover the cost. When this is done, then he is helpless to modify either the time or the terms of payment, or the penalties for failure to pay when due. Congress should so amend the law that authority is given the Secretary of the Interior to suspend the operation of any public notice as applied to any project, part of a project or an individual within any project, when in his opinion such suspension is necessary to make more sure the success of such project, part of a project or individual settler.

Suspensions of payments should not be granted, nor would they be likely to be granted, for the purpose of extending the time for repayment, but only for the purpose of making it possible to pay more surely, and finally more quickly. The present law is rigid as to amount of annual payments and the time for making them. High-cost projects, even if crop returns are low,

must make repayment as fast as the more favorably situated projects where costs are lower and crop returns greater.

Repayment Based on Crops—Terms of repayment should be such as can be met by the ordinary individual who uses due diligence and is otherwise qualified to succeed under normal conditions, and then he should be required to make his payments. If disaster or other unusual conditions should prevail against an individual or group of individuals, it is useless to insist on the impossible being done; some measure of relief should be provided, and it should not be necessary to ask that Congress pass special laws to cover such cases as they come up. It would seem wise for the terms of repayment to be based on the average returns per acre on the different projects or units of a project. Payments based on a percentage of the gross returns from the farm could be met, with the possible exception of individual cases where some unusual conditions prevail, such as complete loss by hail or some crop disease that might ruin a crop. Such unusual conditions could be determined easily, and, where no such conditions exist, payment should be insisted upon and no leniency exercised.

Under such a plan payments would be made as fast as it is possible for them to be made under any kind of plan, for the reason that they cannot be made unless it is possible for the farmers to make them, no matter what the terms may be under the law. It would do away with the periodical requests to Congress for deferment of charges, make it possible to pay, and give encouragement to those who have to do the paying, for they would know that they could, with reasonable industry, pay as much as they would be required to pay.

Briefly summed up, the Secretary of the Interior should have the power to suspend any public notice and the terms of payment should be based on the returns from the farms. Such a plan is businesslike, is workable, and should be tried out. Under it reclamation by the government can succeed, and it will be shown that it was not a mistake on the part of the government to use its funds for the purpose of building homes where none existed before.

Repairing a Lift Span Bridge

THE counterweight cables of the Halsted St. lift bridge in Chicago were renewed in 1922 after being in service 28 years. F. H. Avery, engineer of bridge maintenance, in the latest annual report of the city engineer makes the following reference to the work:

The cables were in good condition, except at the lower end where they were fastened to the top chord of the span. At this point they pass through a long clamp and around a pin. Upon removal, the portion passing around the pin was found to be in a dangerous condition with about one-half of the strands broken, the ends of these strands being corroded until they were as sharp as needles.

The work was done without interrupting traffic, the span being closed to river traffic for the time necessary to change two cables each on two diagonally opposite corners. This change at first took 10 days, but this time was reduced finally to 4 days. Sixteen cables were changed in all and work continued in zero weather, accompanied by high winds, which speaks well for the mechanics. This winter work was made possible by building shelters for the men at the tops of the towers. During the periods the span was closed to navigation, work was carried on continuously with two 12-hour shifts, which, of course, increased the cost (\$22,062.19) of the work.

English Roads and London Traffic

By Paul Wootton
Washington Correspondent, *Engineering News-Record*

The material for this article was gathered by Mr. Wootton while on a trip through England and France to study recent developments in highway construction and traffic regulation.

UNEMPLOYMENT and the urgency of the need to effect economies in transportation are the two outstanding influences which are stimulating highway activities in the British Isles. Were it not for these compelling influences, road work certainly would languish because there is much popular clamor against such expenditures when the rate of taxation already is very high.

Road work is proving to be one of the most effective media in providing employment, since more unskilled and inexperienced labor can be used than in many activities. Some contend that costs are being carried to a prohibitive level and the quality of the work impaired by the use of many inexperienced and even physically defective men, but those in charge of the work declare that the laborers are unusually willing to do the best work of which they are capable and they have figures to show that the average progress of the work compares favorably with that of other years.

Scarcely second in importance in stimulating road improvement is the need for cheaper transport. For more than two years a considerable percentage of Great Britain's manufacturing capacity has been idle. In many instances a small reduction in production costs would have made it possible to compete, or in the case of an operating concern, would have increased profit, and the volume of production. The cost of inland transportation is very high. Even where good roads exist, there has been such congestion as to offset the advantage. The far-seeing men directing public policies—among whom may be numbered Stanley Baldwin, the premier—have insisted that traffic conditions must be improved as a necessary step in the revival of industry.

Constructing New Routes—Col. C. H. Bressey, the chief engineer of the Roads Department of the Ministry of Transport, is directing a bold policy of blazing entirely new routes rather than trying to widen existing thoroughfares in cities and towns. This policy has been carried out in enough instances, Col. Bressey assured the writer, to demonstrate its practicability. In doing this it has been necessary to overcome strenuous objections from some of the property owners and others who fear loss of importance to existing avenues of traffic. While property owners are inclined to be very insistent that their particular roadway be improved so as to carry additional traffic, they frequently are not disposed to be generous in their ideas of the worth of that portion of their property necessary to the widening of the thoroughfare. In that connection, however, it was stated at the Ministry of Transport that in many cases the enhancement of values through the widening of the street offsets the loss of area. There are so many cases, however, where the additional width desired leaves lots without sufficient depth to be used to advantage, that the practice is tending more

and more to roadways around rather than through towns and villages.

Col. Bressey favors building these roads where the maximum of their course can be run through open fields. The owners of country acreage usually are more than willing to give the necessary right-of-way for the road and in many instances will also contribute to the project. This bypass policy, as it is termed in Great Britain, has the additional advantage of preserving landmarks and the ancient appearance of places—an aspect of the situation to which much importance is attached in the British Isles. All the trouble and expense of conducting construction activities among water mains, street-car tracks and wire conduits are avoided, as is the interference to traffic.

In the United Kingdom, as in the United States, the matter of road location and the question of which road is to be improved results in bitterness of the most intense variety. The problem is the more complicated in Great Britain because of the amount of authority vested in local officials, and because of the very large numbers of such authorities. Greater London, for instance, has 122 local authorities who must be approached and consulted on road matters which affect their jurisdiction. (London proper is confined to an area of 1.4 square miles, having less than 15,000 actual residents, despite the fact that it has a day-time population of more than 2,000,000.)

Negotiations with Local Authorities—One of the reasons for the success which has attended Col. Bressey's administration is said to be the skill with which he has handled these negotiations with local authorities and those pertaining to road location. The secret of whatever success he may have had in that direction is attributed by Col. Bressey to the care which has been used in the selection of the men who have to do with public relations. It is his policy not to put a man in a place requiring broad judgment unless that man has had wide experience. Regardless of the earnestness of the man who has confined his work to his own village or city, Col. Bressey believes his results will suffer because of the lack of the broadening influence of wider contacts.

Trouble with Slippery Roads—In addition to the outcry from those whose vision is limited, against the expense of road improvement, Col. Bressey has had to meet from farmers and wagoners an unbelievably insistent objection to slippery roads. The horseshoers have failed to take into account the changes incident to new road surfacing. The shoe most in vogue does not give a sure footing to the horses. As a result, they are prone to fall frequently. The attention paid to this protest by the authorities and the legislators is hard to understand, especially as 95 per cent of the tonnage handled on the roads of England is in motor vehicles. Despite that fact, the horse is much in evidence throughout the Island. In London their number is so great as to constitute a major cause of congestion. Every effort is being put forth to acquaint the owners of horses that slipping can be avoided by proper shoeing.

The spreading of fine gravel on the roadways, on hills and at sharp curves does away with much of the skidding on the part of rubber-tired vehicles. In London steel bins for gravel are erected at frequent intervals. Just as soon as rain begins to fall, the street-cleaning

force scatters this material over the street surfacing. This practice very materially reduces the number of accidents from skidding. While England makes a larger proportional use of concrete, for general purposes, than does any other nation, there is very little traffic carried on concrete surfaces. The use of roads by a large number of steel-tired vehicles leads Col. Bressey to believe that a resilient surfacing should top the concrete. Experience in England also leads to the opinion that solid rubber tires, after short usage, are almost as destructive to a non-resilient surfacing as are steel tires.

London Traffic Problem—London still is temporizing with the traffic problem, but has come face to face with the necessity for improved practice. During the twelve months ended with May, the latest figures available, the number of motor cars in Great Britain increased by 25 per cent. Of that increase commercial vehicles contributed 11 per cent. This rapid growth in the number of motor vehicles, the failure to co-ordinate street repairs, the large use of buses, the disinclination to scrap horse-drawn vehicles and the absence of parallel streets combine to constitute a traffic problem of unusual difficulty.

The number of motor vehicles per capita still is much less than that in the United States. Indications are, however, that the increase in the number of automobiles will continue at an increasing rate. An important contributing factor to the increase is the very material progress which is being made in road improvement. It is very evident, however, that the number of motor cars cannot continue to increase much longer before determined steps must be taken if traffic is moved at even an approximation of an efficient rate of speed. The speed of operation of London buses, in the business district, has decreased from nine to seven miles per hour within the last six months.

No small part of the traffic tie-ups and the congestion on principal thoroughfares, which has come in for world-wide publicity in the press and on the screen, is chargeable to street repairs. This activity is vested in numerous local authorities who are very jealous of their prerogatives. The parochial boundaries date from the time of King Alfred. The wonder is that the 28 separate cities making up greater London get along as well as they do, but it has been evident throughout the past summer that they are not pulling together in the matter of street repairs. In a city with as few alternate routes as has London, there is unusual need for carefully centralized planning as to the streets that are to be torn up simultaneously. Necessity brought about centralization of police authority. It is expected that a similar step must be taken sooner or later in handling the problems arising from the evolution in transport.

Street repairs were carried on this year on a larger scale than usual. It can be said also that the work is being done with greater thoroughness and with a view to a greater degree of permanency than has been undertaken heretofore. This has resulted in withholding from traffic for longer periods the streets under repair.

Wide Arterial Streets—The bold plan of the Ministry of Transport for driving wide arterial streets into the metropolitan area will do much, when complete, to keep through traffic away from the busy streets in the heart

of the city, but by the time those roads are ready the number of vehicles probably will have increased to such an extent that much additional relief will have to be furnished.

Resort to one-way streets must remain limited since parallel streets are few. Many think the only wise way to meet the problem is to embark upon an extensive campaign of street widening. That proposal is surrounded by unusual difficulties, due to the enormous value of property along many of the thoroughfares most in need of relief. Even if such an expenditure were justifiable, the widening process would be limited at many points by edifices which would not be altered because of their historic and sentimental value.

The presence on the streets of London of 3,500 motor buses, a number to which fifty new buses are being added weekly, augments the problem materially. These buses make frequent stops. The stops often halt the entire stream of traffic following, because at most points the street is too narrow to accommodate the stream of traffic moving in the opposite direction and still leave room for vehicles to pass so large a unit as an omnibus. While the buses are responsible for some of the congestion, they do not contribute to it nearly so much as do the horse-drawn vehicles. The business situation at this time is such as to preclude any abandonment of horses or horse-drawn vehicles. So long as they can be continued in service it saves their owners the capital outlay necessary to the change to motors. Animal traction is being abandoned in practically every instance, as fast as the existing equipment wears out.

Steam-driven traction engines with trailers ply all London streets, even during the rush hours. While the presence of these large units, with belching smoke stacks, presents a rather formidable appearance in a traffic jam, they are better handled than are many motor trucks and contribute no more than the latter to congestion.

Congestion at Intersections—The handling of traffic at street intersections is not well performed. While an adequate number of policemen are stationed at these points, tangles are frequent and at the rush hours there is no certainty as to the length of time that will be required to negotiate any of the crowded streets.

A glance at the plan of London is all that is necessary to show how few alternate routes can be chosen for traffic. An unusual number of streets are blind. A thoroughfare starting out to be a parallel street may spread quickly to an unbelievably distant point from the street it may have paralleled for a portion of a block.

Day Labor Tunnel Costs in Chicago

Since 1919 work on the 12-ft. Western Ave. water tunnel has been under way. In the 1922 annual report of the water department just issued excavation progress on 7,977 lin.ft. at the Wood St. shaft is given as 10.81 ft. per 8-hr. shift, at a cost of \$55.52 per lineal foot including labor and explosives. Trimming 9,224.6 ft. cost \$1.05 per foot. Placing footing walls in 7,730.8 ft. cost \$1.65 per lineal foot. Lower figures were obtained at the Sixty-First St. shaft where 9,778 ft. were driven at a cost of \$54.06 per foot, 5,327 ft. of footing walls placed for 83c. and trimming 6,957 ft. cost 41c. per foot.

Chicago Union Station Forms Double-End Terminal

Heavy Traffic Served by Two Sets of Stub Tracks on Opposite Sides of Concourse—Low-Roof Trainshed With Raised Skylights—Tracks on Concrete Base—Office Building Utilizes Air Rights

PROMINENT among great modern railway passenger terminals will be the new Chicago Union Station, which is now entering the final stages of its construction and which in size, traffic and facilities will rank with the two great terminals at New York and the one at Washington. Initiated in 1914 and interrupted by war, protracted strikes and industrial and commercial disturbances in addition to railway difficulties, it is now expected to have the new station completed in 1924.

Distinctive features of this new Chicago terminal station are as follows: (1) In spite of its large size it has tracks, concourse and all main station facilities on the same level, instead of having the more usual double-deck arrangement; (2) it is said to be the largest one-level station ever built; (3) it is a double-end terminal,

being erected by four large guyed derricks, while stiff-leg derricks place the masonry. Beyond the headhouse is Adams St., with the old station building, a truss bridge over the station tracks and a swing bridge over the river. In Fig. 2 is shown the old steel trainshed in process of removal in August, 1923. This view shows the old through tracks, but in the new station the space shown will be occupied by a concourse between two sets of stub tracks. At the left is the old brick headhouse, but the new headhouse is in a different location. A plan of the new station and adjacent railway structures is shown in Fig. 3.

During the ten years of work and delay in the carrying out of this project there have been changing conditions leading to successive developments of the original plans. The most conspicuous of these developments has been in the design of the headhouse, which is now to be a lofty office building to utilize the air-rights of the site, instead of being a low structure for railway purposes exclusively, as originally planned.

Two special features in addition to the station itself are: (1) Extensive and costly auxiliary works necessitated by the taking of land formerly occupied by various railway and industrial activities; (2) a great amount of reconstruction of streets, bridges, sewers and other adjacent municipal facilities and public service utilities, as indicated in *Engineering News-Record*, Feb. 3 and May 18, 1916, pp. 212 and 948, and March 13, 1919, p. 528. Of no less interest and importance are the numerous construction problems and difficulties encountered in carrying on such complicated work in and around the congested conditions of an outgrown railway terminal in a busy city district.

Traffic Conditions—Daily traffic at this station averages 123 main-line trains and 132 suburban trains in and out, with 14 and 24 trains respectively during the busiest rush hour. The number of passengers averages 25,650 daily, 11,500 of these being main-line and 14,150 being suburban passengers. Furthermore, about 4,750 pieces of baggage are handled daily. For New York, official figures give 133 main-line and 225 suburban trains daily at the Grand Central Station, and 181 and 310 respectively at the Pennsylvania R. R. Station. But the record number of trains appears to be held by the old South Station at Boston, with 344 main-line and 297 suburban trains daily.

Double-End Terminal—A double-end station having two groups of stub tracks and platforms arranged end to end but separated by a broad concourse or transverse platform is the unique plan adopted to meet the particular operating conditions. Different railroads use opposite ends of the station and the old arrangement consisted of three through tracks and five stub tracks at the north and south ends, with a concourse on one side of and parallel with them. This through-track plan is objectionable, however, and could not be permitted in a busy modern station, since it not only requires passengers to cross tracks at grade in going to and from the trains, but it also tends to confuse them in finding the right platform and train.

In both the old and new stations the tracks are below the street level. The old headhouse has the waiting

Beyond the headhouse is the Adams St. bridge over tracks and Chicago river, with the old station building at Adams and Canal Sts.

with two sets of stub tracks abutting on opposite sides of a wide transverse concourse; (4) platform tracks are arranged singly instead of in pairs; (5) passenger and baggage movements are kept separate by assigning alternate platforms for these respective uses; (6) a concrete base under the approach tracks will minimize maintenance work; (7) air rights are utilized by a lofty office building over the headhouse; (8) the trainshed is of the low-roof type but with high longitudinal skylights; (9) compact position-light signals eliminate the usual semaphores; (10) extensive alterations to streets, bridges and public utilities were required; (11) construction work was carried out with little interruption to railway traffic or street traffic.

A view of the station under construction is shown in Fig. 1. The headhouse, surmounted by an office building, occupies an entire city block. Its steel frame is

(M) Old headhouse of Union Station.

room and ticket office on the upper or street level, and it would have been possible to incorporate this arrangement in the new station by building the concourse as a bridge over the through tracks, with stairs or elevators to the platforms, as in the union stations at St. Paul and Kansas City. But in the design of this new Chicago station, to handle a heavy main-line and suburban traffic averaging a total of 255 trains in and out during 24 hours, it was considered by far the most desirable arrangement to locate all the main facilities at the track level. Then with the waiting rooms, ticket offices, baggage checking room and cabstand all at the track level, the logical track layout was the double-end stub plan described above and shown in Fig. 4.

A single through track on the east side provides for transfer movements between the two parts of the terminal. Beyond this are two through tracks of the Pennsylvania R.R., which road has two divisors using opposite ends of the station and therefore requires a through line. The site extends to the river, along which is built a concrete bulkhead or dock wall of gravity section supported on four rows of 35-ft. wood piles. Columns on this wall will support a driveway at street level, covering the through tracks.

Tracks and Platforms—In the south end of the station there are fourteen stub tracks with platforms of various lengths for trains of 7 to 18 cars, with their locomotives, allowing 70 ft. for each car. In the north end there are ten stub tracks and the platforms provide for 9- to 18-car trains. The total car capacity of the platform tracks is 191 cars in the south end and 141 cars in the north end.

Single tracks alternating with comparatively narrow platforms constitute an unusual station plan. This arrangement was adopted in order to keep all trucking clear of the passenger movements, each alternate platform being assigned for handling baggage and express exclusively. In the original design this plan was proposed, but in order to secure the maximum number of tracks in the given width of property it was at that time abandoned in favor of the more usual arrangement of tracks in pairs, separated by platforms 16 ft. 3 in. in width, each platform to be used for both passengers and trucking. In this second or modified layout two tracks of each group were assigned for loading and unloading mail. But these tracks were released later for general station purposes by the decision to construct a separate railway mail station, the location of which is shown in Fig. 3. This structure was described in *Engineering News-Record*, Dec. 22 and 29, 1921, pp. 1011 and 1058. Mail cars are switched between this station and their

trains standing in the passenger station. On further study, therefore, it was decided to revert to the original plan of single tracks and separate platforms for trucking. In the adopted layout, Figs. 4 and 5, the widths of passenger and trucking platforms are 13 ft. 9½ in. and 10 ft. 9 in. respectively, with alternate track spacings of 23 ft. 3 in. and 21 ft. 6 in.

Low platforms are used, although high platforms approximately 4 ft. above the top of rail were planned originally, following the type of construction used in the Grand Central and Pennsylvania terminals at New York. Although there were advantages in this latter plan, particularly in the convenience of passengers and the less vertical distance to be overcome between the car and the street, it was abandoned largely on account of the great cost of altering car equipment to adapt it for use at this one station. As constructed, the height of edge of platform above top of rail will be 7½ in. for the passenger platforms and 20 in. for the baggage platforms. Since the passenger platforms are about 4 ft. below the concourse elevation and are reached by ramps having an inclination of 6.37 per cent, it is practicable to build high platforms later, if desired, without altering the present concourse.

The platforms will consist of reinforced-concrete slabs resting on concrete side-walls which are built on a 10-in. foundation slab of plain 1:3:6 concrete. Slabs for the passenger platforms are 6 in. thick at the sides, with a

FIG. 2—REMOVING OLD TRAINSHED OF CHICAGO UNION STATION

Station opened in 1880. Old headhouse and Adams St. viaduct at left. Swing bridge for Adams St. over Chicago River at right. During removal of trainshed traffic was handled temporarily on additional tracks between trainshed and river.

crown of 1½ in. at the middle and having ribs on the underside to lock with the side-walls. Slabs for the baggage platforms are 8 in. thick at the sides and have a slope of ½ in. in 12 in. from the center line. The underside is flat, without the ribs used on the passenger platforms. In all platform slabs the upper edge is finished with a curb bar with a radius of 1 in. A solid fill of sand or cinders is placed under the platforms, except that under some of the baggage platforms the space is left open to serve as a gallery for pipes, wires and other utilities. Temporary plank decks level with the rails were provided on some of the new platforms first put in service (see Fig. 4).

The separate trucking platforms will facilitate baggage handling materially, for with the baggage room placed beneath the concourse it can be connected with these platforms by ramps, the slope of which is 6.75

per cent. This arrangement eliminates the delay, first cost and operating cost incident to the use of elevators at the ends of the platforms to raise and lower baggage trucks. With the adopted arrangement, tractor-trailer trains will operate directly between the cars and the baggage room. An incline from the street on a grade of 4 per cent will lead to a driveway alongside the baggage room, with 380 ft. of tailboard space, so that wagons or motor trucks can receive and deliver baggage directly, without requiring elevator service.

Track Approaches—At each end of the station yard a six-track main line approach is provided, with tracks spaced 13 ft. c. to c. As the approaches are approximately in line with the east side of the station, the usual V or fan-shaped connection with the platform tracks is replaced by a double-track diagonal ladder, with slip and split switches enabling any approach track to

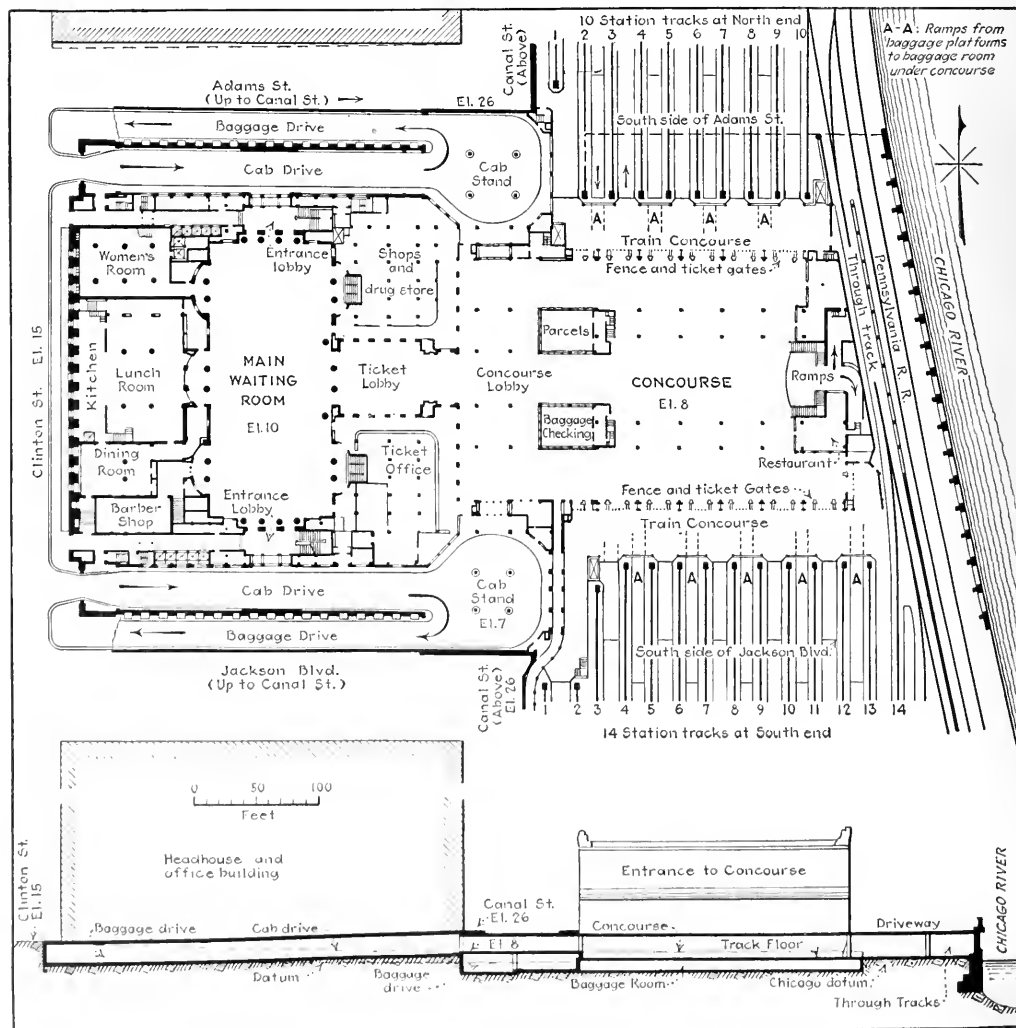

FIG. 4—PLAN OF HEADHOUSE, TRACKS AND PLATFORMS

FIG. 5—TRAINSHED AND PLATFORMS, CHICAGO UNION STATION

be connected with any one of the platform tracks. Part of the south approach is shown in Fig. 6. There are thirty-three double slips and nine diamond crossings in the south yard and sixteen slips and six diamond crossings in the north yard. All slips are No. 8 or No. 9 and have movable-point frogs.

Track Construction—A concrete slab roadbed is another special feature of the station, this construction being provided under the ladders and slip switch connections and on part of the main-track approach. Since the subgrade elevation is only about 4 ft. above the water level in the Chicago River, which is close beside the tracks, the roadbed will be of necessity somewhat soft, in spite of drainage. Under the pounding of heavy loads, especially at the frogs and switches, the ballast would gradually be driven into the roadbed, so that continual work would be required in surfacing and adjusting track. Such work would be slow and costly, owing to the heavy traffic. It would also interfere more or less with train movements and would involve hazard to the trackmen.

In order to provide against this condition, the roadbed is covered with a 10-in. slab of reinforced concrete on 12 in. of cinders. The surface of the slab is approximately at subgrade level, but is formed in drainage planes, with sumps connected to a system of tile under-drains and served by automatic electrically operated pumps. Upon the slab is crushed stone ballast 8 to 10 in. deep under the ties. Where the concrete slab is not used the ballast is 12 in. deep under the ties. This unusual roadbed construction was described in *Engineering News-Record*, July 29, 1920, pp. 193 and 233.

In the station, each track has a reinforced-concrete slab, shaped to form a central drain, with creosoted red-oak or yellow-pine blocks embedded along each side, as shown in Fig. 7. These blocks are 6 x 8 x 30 in., spaced twenty to each 33-ft. rail. They are fitted with shoulder tie-plates 7 x 11 in. and $\frac{3}{4}$ in. thick, each plate being held in place by two spikes while two other spikes form the rail fastenings. These platform tracks have 100-lb.,

33-ft. rails. On the approach tracks, 130-lb. rails are used, in 33-ft. lengths, spliced with four-bolt angle bars 24 in. long. Shoulder tie-plates as described above are placed on all ties and the rails are secured by $\frac{1}{2}$ -in. drive spikes. All ties are of red oak, treated with zinc-chloride or creosote. The 10-in. slab under each track, with a width of 14 ft., is of 1:2:4 concrete. Above this, the concrete forming the track surface is a 1:1 $\frac{1}{2}$:3 mix with a $\frac{1}{2}$ -in. cement finish.

Except for the slips and crossings, which were designed by the engineers of the Union Station, all track material is of Pennsylvania R. R. standards. Special work is avoided as far as possible in the complicated turnouts and switch layout. At the slip switches, the end frogs have manganese centers and cast steel heel and toe blocks bolted between ordinary rails. Switch rails are 15 ft. long with 4-in. throw; movable-point frogs are 12 ft. long with 4-in. throw. Anchor straps, fastened at the heel joints of the rails and to the five ties on each side of the joint, or twenty ties in all, effectively prevent any creeping at switches. In the No. 8 slip switches, the length is 54 ft. 7 in. between switch points and 76 ft. 11 in. between the frog points of end frogs. Frog guard rails are of cast manganese steel. Main tracks on the approaches are spaced 13 ft. c. to c. The sharpest curves on these approaches are 12 deg. at the south end and 13 deg. 17 min. at the north end.

Signals and Interlocking—Design and location of signals constituted a special problem. With the complicated track layout and the limited lateral clearances, as well as the numerous low-level bridges across the tracks, giving only 17 ft. headroom, it was practically impossible to locate supports for signal bridges at the proper positions to allow full track capacity. To meet this difficulty, posts and semaphores are eliminated and the entire equipment consists of high and dwarf position-light signals. Dwarf signals are provided at the throat of the station, where all movements through the switches are made at low speed. High signals are used where the movements are numerous but generally with-

out diverging from one track to another. These latter are placed conveniently on the track sides of the parapet walls of street bridges which cross the tracks.

Position-light signals were adopted in preference to color-light signals, mainly for the reason that the former permit of a larger number of indications with a minimum size of signal. The indications are shown in Fig. 8. A new development in signaling is the four-position dwarf signal, giving the following indications: (1) "Proceed," two lights in a vertical line; (2) "Proceed under control," two lights in a 45-deg. line below the horizontal; (3) "Caution, prepare to stop at next signal," two lights in a 45-deg. line above the horizontal; (4) "Stop," two lights in a horizontal line. The second or permissive indication enables trains on the same track to follow each other with safety.

High signals on the approach have each seven lamps giving five indications by the arrangements shown in Fig. 8. The permissive signal indicates that the track immediately ahead is occupied but that the train may proceed prepared to stop at once. The slow-speed signal means that the route is set to diverge over a slow-speed

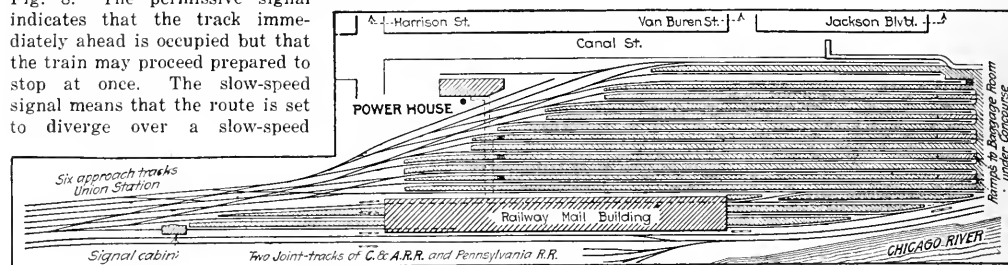

FIG. 6—TRACK LAYOUT OF SOUTH APPROACH

turnout. The caution signal is a warning that the next signal is at "stop." Switch and signal movements are controlled from two towers, one at each end of the station.

Low-Roof Trainshed—A steel-frame trainshed of the low-roof type was adopted after consideration of different types. This is in accordance with general modern practice, but for the Chicago station it was considered desirable to provide greater lighting and ventilating facilities than are provided in some low-roof trainsheds. In the design adopted, therefore, the low roof with open smoke duct over each track is supplemented by a high triangular ventilated skylight over each passenger platform and a low monitor skylight over each baggage platform. This arrangement, shown in Fig. 5, is somewhat similar to that of the trainshed of the Indianapolis Union Station (*Engineering News-Record*, July 10, 1919, p. 84, and Aug. 19, 1920, p. 351). The Indianapolis trainshed, however, does not include the continuous low skylights, since the tracks are arranged in pairs and special baggage platforms are not provided as at Chicago.

Columns supporting the transverse curved roof ribs are spaced 41 ft. 8 in. c. to c. along the middle of each passenger platform. They give a transverse span of 44 ft. 9 in. c. to c. of columns, with clearance line 17 ft. above top of rail. Longitudinal arched ribs are framed between the columns and support intermediate transverse ribs, thus minimizing the number of columns. Longitudinal girders framed between the ribs form the sides of the smoke ducts and will be cased in concrete for protection against corrosion. Instead of the smoke ducts being of uniform width, as is the usual arrangement, they are reduced from 32 in. in the lower portion

to 18 in. in width at the top. This is done to afford the platforms additional protection against driving rain or snow, while it provides ample area for ventilation and for the escape of blast from the engines.

Cement tile laid on steel framing and covered with waterproof composition roofing will form the main part of the roof. Wire-glass tiling will be used in the high and low skylights, the glass being of a special tint selected after extended experiments to secure absorption of heat rays and thus avoid excessive heat in the trainshed during hot summer days.

This trainshed, covering both groups of terminal tracks and the concourse between them, will be 2,380 ft. long, with a width of 180 ft. 6 in. for the north yard and 250 ft. for the south yard. It will not extend over the three through tracks along the east side of the station, these tracks being covered by a driveway along the river front. For platforms built previous to the erec-

tion of the trainshed, temporary butterfly roofs of timber construction are provided. In the old station a steel truss trainshed with trusses of 66-ft. span on columns spaced 24 ft. 10 in. longitudinally covered five tracks and platforms. It was 34 ft. high from rail to top chord of truss. This structure, shown in the course of removal in Fig. 2, has been repaired and reinforced in recent years, owing to severe corrosion of some of its members, and has now been dismantled.

Headhouse Forms Office Building—In the old station, all facilities were east of Canal St. (see Fig. 3), the station building having its front on that street and the tracks lying between this building and a row of buildings (now removed) along the river front. To provide adequate accommodation for the new station, additional property was secured covering an entire block 296 x 320 ft. west of Canal St. as the site for the new headhouse. The river front property was also secured, so that the tracks and platforms will occupy all the space between Canal St. and the river, as shown in Fig. 3. A broad subway under the street will connect the headhouse with the other part of the station.

One of the fundamental features of the headhouse layout is the placing of all main station facilities at the track level, below the street. This arrangement is made the more easy and convenient by the fact that the street level falls west of the station. Thus Canal St., along the east side of the building, is at El. 26; Clinton St., along the west side, is only at El. 15, while the main waiting room is at El. 10 and the concourse is at El. 8. These levels are indicated on Fig. 4. Stairways, elevators and inclined walks and driveways will extend from the street level to the station level.

In accordance with the plan for a one-level station, at

the lower or main level are arranged the tracks, platforms, concourse, waiting rooms, ticket office, baggage room, dining and lunch rooms, cabstand and carriage entrance. On the upper or street level floor of the headhouse are arranged shops and the entrance lobbies to the main waiting room. Among the several special facilities provided is a jail or detention room where prisoners in transit can be held securely and kept apart from the traveling public. Entrances to the office portion of the building are entirely separate from those to the station.

The main waiting room is to be 100 x 217 ft., with a height of 114 ft. to a roof composed mainly of skylights. From this room a lobby 185 ft. wide, with ticket office along one side, will extend under Canal St. to the concourse, which is 190 ft. wide and 280 ft. long. A screen or railing on each side and provided with gates will separate the concourse from the train platform. Outside this railing will be a train concourse 36 ft. wide, by which employees or passengers can pass from platform to platform.

As planned in 1915, this new headhouse was to be a low structure, handsome in architectural design and devoted exclusively to station purposes. An office building was considered, but studies made at that time indicated that the location was not favorable, being several blocks from the business district. In the next few years, however, there was a decided trend of business to extend beyond this limited district and even across the river. Furthermore, financial conditions made it desirable to develop the air rights above the station for revenue-producing purposes.

When the headhouse design was again considered in 1919, at which time work on the terminal was resumed, it was finally decided to erect a 22-story office building over the site. This new design was described in *Engineering News-Record* of Dec. 1, 1921, p. 894, and the lower 8-story section is now under construction. This building will be 374 x 312 ft., with a central light court 132 x 204 ft. over the waiting room, the roof of which will be at approximately the seventh floor level.

Concrete cylinder piers founded on a deep stratum of hardpan at a depth of 60 to 66 ft. below city datum (or water level in the Chicago River) form the foundations for this building. There are 449 of these piers, of which 181 were required by the change to a 22-story structure after the foundations had been built for the low structure originally proposed.

With the redesign of foundations, trouble arose over a suggestion from the city authorities that the foundation should be carried to rock, at a greater depth. A combination of piers founded on rock and hardpan was considered highly undesirable for such a structure, besides which the additional cost for the deeper new piers would have been considerable. To demonstrate the carrying capacity of the hardpan, two piers were built in the usual way and loaded to a maximum of 87½ tons per square foot, with only slight deflection, as described in *Engineering News-Record* of Nov. 10, 1921, p. 763, and May 18, 1922, p. 822. As a result of this test the

FIG. 8.—POSITION-LIGHT SIGNAL INDICATIONS
Black spots show lights displayed for each indication.
Open circles show lamps not lighted.

building commissioner approved the hardpan foundation with a load not exceeding 10 tons per square foot. A somewhat complicated arrangement of concrete girders on the piers is required to distribute the load and to provide supports for the new column arrangement in the larger superstructure.

Power House for Station—A complete power plant and electric generating station was proposed originally as part of the terminal. But in view of the great development of electric utilities in Chicago it has been decided to purchase all electric current. A power house south of the station will supply steam and compressed air service for the terminal, station and office building.

History of Chicago Union Station—The old union station at Chicago, put in service in 1880, was remodeled in 1892 to take care of the prospective heavy traffic of the World's Fair of 1893, since which time it has accommodated the ever increasing traffic with only minor alterations. The original Union Station Co. was formed jointly by the Pennsylvania R. R., the Chicago, Milwaukee & St. Paul Ry. and the Chicago, Burlington & Quincy R. R., with the Chicago & Alton R. R. as a tenant road. The Pennsylvania R. R. was the majority owner, since it had two lines using the station: the Pittsburgh, Fort Wayne & Chicago R. R. entering at the south end and the Pittsburgh, Cincinnati, Chicago & St. Louis Ry. entering at the north end.

Studies for enlargement and reconstruction were made at various times, but it was not until 1906 that a definite plan was proposed and was adopted by the several railways after extended negotiations. This plan was substantially what is now being carried out. It was submitted to the city authorities in 1913, an ordinance was passed in March, 1914, and was accepted by the railroads in June, 1914. Preparation of detail plans was then undertaken, but the opening of the World War halted the project and with the entrance of the United States into the war in 1917 the work was practically suspended.

While the old station occupied an area of about 225,000 sq. ft. with its buildings and tracks, the new plan required nearly 1,400,000 sq. ft., including land occupied by freight houses, team yards, a large electrical power house, large warehouses of wholesale firms and a number of streets with sewers, water and gas mains and the utilities of public service companies.

Before proceeding with work on the station proper, therefore, it was necessary to provide new railroad and other facilities to replace those to be destroyed and also to carry out extensive alterations to streets, bridges, bridge approaches, and various public utilities. As this work was scattered and largely underground it made no great show, so that the public has not realized the progress being made or the vast amount of work

FIG. 7.—STATION TRACK CONSTRUCTION

required as a preliminary to reconstruction of the station. The additional work outside of the terminal has included three large freight terminals, a railway mail station and a 20-story warehouse built for Butler Bros.

Progress on the station proper up to July 31, 1923, included partial reconstruction of platforms, tracks and track approaches, demolition of the old trainshed, and partial erection of the steel frame for the lower portion of the combined headhouse and office building. Work was commenced in 1916, but was delayed by a 10-months strike and postponed indefinitely in the spring of 1917. When resumed in 1919, it was hampered by strikes, car shortages, high prices and the various other disturbances which followed the war period. It is now expected to have all the work completed by the end of 1924.

To carry out this extensive project a new company was organized under the name of the Chicago Union Station Co., in which the Pennsylvania R. R. owns 50 per cent of the stock and the Chicago, Milwaukee & St. Paul R. R. and Chicago, Burlington & Quincy R. R. hold 25 per cent each. The Chicago & Alton R. R. continues as a tenant road. No other railroads use this station. The company has its own chief engineer and engineering department in charge of design and construction, but for the consideration of important technical problems there is a board of advisory engineers composed of representatives of the three owning roads.

J. D'Esposito is chief engineer of the Chicago Union Station Co., and Thomas Rodd (formerly chief engineer of the Pennsylvania R. R.) is consulting engineer. Graham, Anderson, Probst & White are architects for the headhouse and office building. The John Griffiths & Son Co. has the contract for this building, the steel for which is being fabricated by the American Bridge Co. and erected by the Overland Construction Co. Foundation work was done by the R. C. Wieboldt Co. The cost of the station or terminal proper will be about \$60,000,000, including land, trackage, signaling, station facilities and headhouse structure. The total expenditure involved in the terminal reconstruction, including also the new freight stations, railway mail station, warehouses, city bridges, street elevation and miscellaneous reconstruction of streets, viaducts and public utilities, will amount to approximately \$95,000,000.

Mormon Flat Dam to Perform Regulating Service

Work has been pushed actively on the Mormon Flat dam, 27 miles below the Roosevelt dam on Salt River in Arizona. This improvement follows the increase in the storage capacity of the Roosevelt dam from 1,300,000 to 1,600,000 acre-ft. by the installation of 15-ft. gates in the spillway of the dam, which also gives an additional head for power. The Mormon Flat dam is being constructed primarily to increase the water power available to the Salt River Valley. The new dam, however, also performs a regulating service. It has a storage capacity of 90,000 acre-ft. Five power plants now are in operation which delivered 78,000,000 kw.-hr. last year. The construction of the new dam makes possible the installation of an additional 7,000-hp. unit. This improvement is desired because of the wide fluctuation between the minimum and maximum amounts of power now available. To carry out these improvements the Salt River Valley Water-Users Association bonded itself for \$1,800,000.

Bronx Parkway Bridges Tested by Heavy Loads

Withstand Stresses Many Times as Great as Those for Which Intended, Including Weight of 70-Ton Excavator Used on Job

BY ARTHUR G. HAYDEN

Senior Assistant Engineer, Bronx Parkway Commission, Bronxville, N. Y.

THE PARKWAY drive in the new Bronx River Parkway Reservation, which extends from Bronx Park, New York City, to Valhalla, Westchester County, N. Y., crosses the Bronx River at several points and required the construction of about 30 drive bridges. It was originally intended that most of these bridges should be true arches, but the rise in cost of materials following the war led to the adoption for some of the shorter spans of a reinforced-concrete beam type. Some of the bridges have granite arch facing to resemble the much more costly stone arch bridge; others are faced with timbers so as to resemble rustic beam bridges. Some of these structures have had to carry abnormally heavy

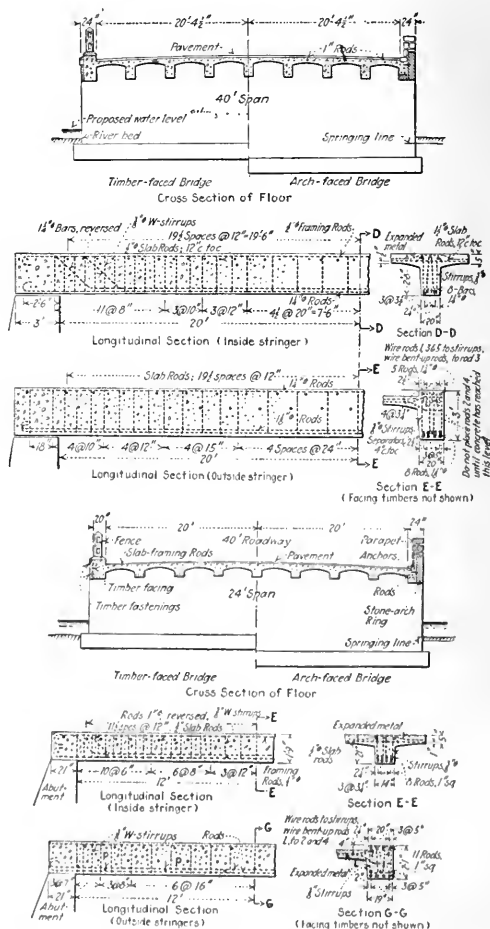

FIG. 1—FLOOR CONSTRUCTION OF BEAM BRIDGES

FIG. 2—TIMBER-FACED CONCRETE BEAM BRIDGE ON BRONX PARKWAY

North of Crestwood, N. Y. Span 35 ft., roadway width 40 ft.

loads, which they did safely. Stresses far beyond accepted limits of safe practice do not appear to have injured them.

The design of all the reinforced-concrete beam bridges was to some extent influenced by the dimensions of steel forms used in the construction of New York City subways, which had been purchased second-hand for Parkway use. Standard designs were made for clear spans of 24, 30, 35, 40, and 45 ft., all 40 ft. wide between curbs. Although commercial traffic will be prohibited in the Parkway, the bridges were designed to carry a concentrated load of 15 tons (including impact allowance) on two axles 11 ft. on centers, which will correspond to the heaviest maintenance machinery. There are no experimental data for determining the concentrated load distribution in floors like these, but judging from tests on floors that were different in design and have smaller stringer spacing it was decided that a fair assumption would be that about 80 per cent of a concentrated load would be carried by the underlying stringer. On this basis the assumed concentrated load would cause stresses of 16,000 lb. per square inch in the steel and 650 lb. in the concrete. Architectural requirements imposed a limit upon the depth of stringers which is less than the economic depth, but every structure has exhibited a great reserve of strength and rigidity under very severe test.

The Parkway Commission owns and operates many heavy pieces of construction machinery which had to be transported over the completed bridges as Parkway

construction progressed. The heaviest is a Monighan 2-T dragline excavator, which weighs about 75 tons, and has crossed several of the bridges. This machine "walks," that is, during transportation it is supported alternately first on a circular base 15½ ft. in diameter and then on two "feet" or walking platforms, one on each side of the machine, each being 3½ ft. wide and 16 ft. long. It imposed a load on the bridge stringers several times as great as that for which they were designed, but none of the bridges which it crossed showed the least sign of distress. Such a test demonstrates the value of attention to the details of design and construction which is necessary to develop the strength of a member.

FIG. 3—DRAGLINE CROSSING CONCRETE BEAM BRIDGE. Structure similar to that of Fig. 1; span 35 ft. A 75-ton dragline excavator of "walking" type is crossing it, overloading the floor several hundred per cent.

For studying the effect of this emergency load, a wider lateral distribution in the floor should be assumed than given by the design rule. With the machine resting on the circular base, 70 per cent of the load is assumed to be carried by the three underlying stringers and distributed along a length of 16 ft. of the stringers, then the calculated stresses are 26,000 lb. per square inch in the steel and 1,020 lb. in the concrete. With the machine resting on the feet, assuming 70 per cent of the load on one foot to be carried by the underlying stringer and distributed along a length of 18 ft. of stringer, the calculated stresses are 34,000 lb. per square inch in the steel and 1,400 lb. in the concrete. Using a factor of 60 per cent instead of 70 per cent the calculated stresses are: with machine resting on the circular base, 24,000 and 960; with the machine resting on the feet, 30,000 and 1,200. The above calculations are for the 35-ft. span, over which the photograph shows the drag-

FIGS. 4 AND 5—TWO ARCHED BRIDGES—STONE ARCH AT LEFT, ARCH-FACE CONCRETE BEAM BRIDGE AT RIGHT

At left, bridge 23, located between Harborside and White Plains; a concrete arch of span 52 ft., rise 12 ft., with stone facing architectural design by Gilmore D. Clark, of Pelham. At right, bridge 13, Bronxville; reinforced-concrete beam bridge of 10-ft. span with arched stone facing; architectural design by C. W. Stoughton, New York.

line crossing. Calculated stresses for the bridges of 30, 40 and 45-ft. span would be nearly the same—a little greater for the longer spans.

On two 40-ft. bridges between Mt. Vernon and Bronxville a 30-ton bucket excavator operated in deepening the river channel, standing at the extreme side of the roadway and handling wet material with a 3-yd. bucket at the end of a 45-ft. boom. Machines weighing 30 tons mounted on caterpillars of narrow tread, have repeatedly crossed nearly all of the bridges.

The commission's engineering department expects to make field tests on one or more of the Parkway bridges to determine, as closely as may be, the distribution of heavy concentrated loads over the stringers.

Kutter's n for Rough Rock Channel Excavated by Explosives

By C. E. RAMSER

Senior Drainage Engineer, U. S. Bureau of Public Roads,
Washington, D. C.

TO THE writer's knowledge Kutter's n has never been determined experimentally for channels excavated in rock by means of explosives where the condition of the channel was similar to that of the Sals Creek Diversion Channel in the Little River Drainage District, Mo., as shown in Fig. 1. Horton's table gives values ranging from 0.025 to 0.035—with 0.033 as the most commonly used values—for canals excavated in rock, which values are no doubt intended for use where the inside of the channel is made fairly regular and smooth. Engineers of the Little River Drainage District used a value of 0.045 in designing the rock cut of the Sals Creek Diversion Channel. Measurements on this channel were made by the writer to determine experimentally the value of n as a check on the design and to afford information for future application. The slope of the water surface was measured along two courses, one 255 and the other 161 ft. long, the latter course being included in the former. Measurements of seven cross-sections of the channel along the slope courses were made. No attempt was made to show the projecting rocks in the cross-sections but points were selected that represented fairly well the size and shape of the cross-sections. The discharge was measured with a current meter for two different stages in the channel with average maximum depths of 5.42 and 5.67 ft.

FIG. 1—SALS CREEK ROCK CHANNEL FROM LOWER END OF SLOPE COURSE

HYDRAULIC ELEMENTS AND VALUES OF n IN KUTTER'S FORMULA Sals Creek Diversion Channel in Rock; Little River Drainage District, Mo.

Elevation Water Surface, Ft.	Average Maximum Depth, Ft.	Average Surface Width, Ft.	Discharge, Sec.-Ft.	Average Cross-Section Area, Sq. Ft.	Wetted Perimeter, Ft.	Mean Hydraulic Radius, Ft.	Slope of Water Surface	Mean Velocity, Ft. per Sec.	c	n
Length of Slope Course = 255 Ft.										
98.33	5.42	10.0	160.0	44.1	17.7	2.49	0.00268	3.63	44.4	0.0385
98.58	5.67	10.1	177.9	46.2	18.0	2.56	0.00288	3.85	44.8	0.0385
Length of Slope Course = 161 Ft.										
98.33	5.61	10.1	160.0	46.2	18.1	2.56	0.00279	3.46	41.0	0.0420
98.58	5.86	10.2	177.9	48.4	18.5	2.62	0.00274	3.68	43.5	0.0395

for the long course and of 5.61 and 5.86 ft. for the short course. The cross-sections are platted superimposed in Fig. 2, from which an idea of the shape, size, and uniformity of the cross-sectional area can be obtained.

FIG. 2—CROSS-SECTIONS OF SALS CREEK ROCK CHANNEL ALONG COURSE OF SLOPE

Values of n in Kutter's formula, and hydraulic elements of the channel, are given in the table from which it is seen that the values of n obtained range from 0.0385 to 0.0420.

Ball Test for Measuring Concrete Quality

At Purdue University investigations have been made into the value of the ball test as a determinant of the quality of cement mortar and of concrete. This test consists in the application by pressure of small steel balls on the surface of concrete, the measure being the depth of impression made for various pressures. In a bulletin of Purdue University by R. B. Crepps and R. E. Mills, the following conclusions are drawn: The ball test applied to cement products affords a valuable and convenient means of determining compressive strength. It is a very reliable index of strength for any age or mix. By means of the test material already in place may be tested. It will be useful to contractors and inspectors in determining accurately when a concrete road may be opened for traffic or the forms removed from a structure. The test indicates a new means of studying the following questions in connection with concrete pavements: (a) effect of wheel loads upon surface strength; (b) effect of different types of tires upon surface strength; (c) effect of tire inflation upon surface strength; (d) distribution of damage on an area of contact; (e) effect of impact, and (f) recovery of surface strength.

Can We Best Do Public Work By Day Labor?

BY L. G. HOLLERAN
PAUL BROWN
CHARLES H. PAUL

The question of contractor versus force account is analyzed here in an article by Mr. Holleran, which was submitted for comment to Mr. Brown and Mr. Paul.

Advantages of Force Account System Favor Its Adoption

BY L. G. HOLLERAN
Deputy Chief Engineer, Bronx Parkway Commission,
New York, N. Y.

WHY NOT carry on all municipal construction by force account instead of by contract? Important public works have been successfully constructed in this way. Among these are the Panama Canal, many of the U. S. Reclamation Service irrigation projects, the flood protection works of the Miami (Ohio) Conservancy District, and the development of the Bronx River Parkway Reservation in New York City and Westchester County, New York.

Statement of Force Account Problem—To do municipal work by force account, a large business must be conducted by the municipality; and any large business, to be successful, must have a permanent organization with a personnel commensurate both in ability and in number to the nature and importance of the business to be handled. The fundamental difficulty lies in building up and maintaining such an organization, owing to the constantly changing policies of municipal administrations and the likelihood of political interference.

Construction work in general is a manufacturing business, but, unlike factory operation, it is not generally susceptible of standardization beyond a rather moderate degree. It is a manufacturing business where different types of machinery and different materials are used, not for each job only but often for each operation. The selection of the machinery and often the selection of the materials, or some of them, is a matter of judgment which must be exercised not at considerable intervals as in factory operations, but daily and hourly. In other words, construction on a large scale is not only financially hazardous, but it requires for its economical and successful conduct the highest skill and judgment, not by a few men but by many men, often widely scattered and therefore not under the continuous and sustained control which can be exercised in factory operations where the organization is centralized in the factory buildings.

The two phases of the problem touched upon emphasize the necessity for mature deliberation on the

feasibility of force account in any particular case before any attempt is made to adopt it. The conditions which may be considered favorable to adoption are noted in the adjacent panel.

Advantages of Force Account—Assuming that favorable conditions exist, let us consider the advantages to be expected:

(1) There should be a very considerable saving in time. Under the contract method, the contract and plans must be printed, and then approved; the contract advertised; bids taken and canvassed; bidders investigated, and contract and bond executed and delivered

before work can be started. At least two months is the average time for this procedure and often it takes much longer. If the municipality were doing the work with its own forces, it could begin before all the detail plans were made, and the cost of printing, advertising, investigating, etc., would be eliminated. The cost of the bond and a considerable proportion of the cost of workmen's compensation insurance would also be saved, as municipalities would in most cases become self-insurers, and would be able to insure themselves at a fraction of the rates charged by the casualty companies.

(2) Changes in plan under the contract method usually mean additional cost and often a delay in completion. By force account both the delay and generally the additional cost would be eliminated; in fact the cost of the work might often be decreased by judicious changes in plans. It would also be possible to make many advantageous changes in plan which are not now made because the advantages to be expected are disproportionate to the delay and cost involved.

(3) Contractors seldom complete work within the contract period and very often meet with financial or other difficulties which make it necessary to re-advertise the work. This procedure often delays completion for months or even years. Failure of a contractor almost invariably means litigation and financial loss to the municipality as it is difficult, if not impossible, to collect from the surety.

(4) Under the contract method, the municipality loses any benefit from a drop in the price of labor and materials during the life of a contract.

(5) There would be better control as a whole of work under construction. If conditions arose where one

Five Requirements for Success

As Set Forth by

L. G. HOLLERAN

(1) Assurance that the organization will be entirely unhampered by political interference.

(2) A municipal administration in sympathy with the method and ready to support it against attempts at political influence and against unjust criticism.

(3) Willingness to pay salaries commensurate with the ability required for successful operation.

(4) A construction program of such magnitude and planned ahead for such a time as to allow a reasonably large and permanent organization to be built up and maintained.

(5) Absence of restrictive laws and regulations, including civil service regulations, which would hamper the conduct of the work by this method.

piece of work was badly needed, it could be expedited at the expense of delay on another piece for which there was not such immediate need. This would not generally be practicable where the two pieces of work were under separate contracts.

(6) The cost of engineering and inspection service could be considerably decreased. It would not be necessary to make measurements and computations for progress estimates, and while it would not be possible to eliminate all inspection service, it need not be so severe nor expensive.

(7) With a large construction program and practically unlimited credit, the municipality would be able to purchase materials and supplies in quantity and therefore to better advantage than any except the very largest contractors.

(8) Probably the greatest advantage under proper and able management, would be providing work to take care of unemployment in slack times.

(9) Another great advantage would be the conduct of maintenance work on a more economical basis than at present by the interchange of forces and machinery between the construction branch and the maintenance branch.

Disadvantages of Force Account—There are obvious objections to force account construction:

(1) Most men look upon the expenditure of public funds differently from the way they look upon the expenditure of the funds of the individual, firm or corporation which employs them. They seem to lack power to visualize any particular one to whom they are required to account, and since no one person is going to be very much injured by lack of strict economy, they do not strive for economy.

(2) In the very nature of things there is bound to be a lack of incentive to produce economical work. In the first place, the funds of the individuals in charge of the work are not at hazard. If a contractor's costs for any item of work are higher than the bid or higher than he expected, he is naturally most anxious to find out why and to remedy conditions. Generally he puts forth the necessary effort to find a solution of the problem and lower his costs. Indeed his business life will often depend on finding the proper method. The case of the man in charge of construction of public works by force account is different. His business life will in all probability continue just the same whether or not the costs are within the estimate. It is far easier for him to say "we are doing the best we can" than to make that determined effort to lower costs which actually lowers them in the case of the contractor.

(3) Of much the same import is the lack of competition. Contractors know that in order to obtain a contract, their bids must be reasonable, and generally they are. Often they are too low which is bad for the municipality, and bad for the contracting business. Therefore, while competition has its merits, too keen competition, which leads to a bid lower than the price for which good work can be done, also has its adverse points. Moreover, competition can be developed under the force account method. Different superintendents and different foremen can compete against each other on items that are alike or comparable, bonuses can be offered for low costs and in time an organization, which would be eager to produce work at the lowest possible cost, can be built up.

(4) The municipality would have to stand the increased costs due to any rise in the price of labor and materials, such as might not have been foreseen by a contractor bidding on the same work. In the long run, a municipality would probably break even on the rise and fall of prices because it would also have the advantage of prices lower than those prevailing at the time the estimates were made.

(5) There will always be special and infrequent forms of structures or works requiring special equipment or especially trained workmen, which it will be more economical to contract for than to build by force account, because the infrequent use of special machinery would allow it to deteriorate rapidly and the machinery charges for such work as could be done by it would be much higher than the same charges to a contractor who has such equipment in continual use.

Small-Scale Test Inadvisable—Force account cannot succeed on a small scale for the reason that there would not be sufficient work to justify the employment of competent and able men to organize and supervise the labor force. The experiment would, therefore, be more likely to prove a failure than otherwise. If tried at all, it should be on a scale which would justify the employment of competent men and the purchase of adequate machinery and equipment for the classes of work to be undertaken.

On the other hand, it would not be possible to organize a labor force, purchase machinery, equipment and materials and take over all of the construction work in the larger cities on any certain date. The change would have to be made gradually; first taking over the paving, say, and then the construction of bridges, then the construction of docks, etc., with sufficient intervals between to allow the previous classes of work to get on a good working basis.

The magnitude of the construction business which would have to be organized in the larger cities is such as to fire the imaginations of the ablest organizers in the country. The head of the construction department in New York, Chicago, Philadelphia or San Francisco would have to be as capable as the presidents of our largest railroad systems or the general managers of the greatest manufacturing corporations.

If ably managed, such organizations would be schools for the younger generation of engineers and construction men, offering such a variety of experience as has never before existed in one organization in this or any other country. They could also well afford to maintain laboratories for research work in the use of new materials, new methods and labor and material saving designs for structures and equipment. Such laboratories are badly needed in this country if we are not to be excelled by foreigners in fields which we have heretofore considered peculiarly our own.

Conclusion—It is submitted that the organizations mentioned at the beginning of this article have demonstrated that the construction of public works of large magnitude can be economically and substantially carried out by force account, and it is thought that most of those familiar with present procedure will agree that there would be decided advantages in so constructing such works where favorable conditions exist or can be brought about.

The question whether or not the force account method can be generally adopted in view of the grave difficulties in the way of organizing labor forces which

could or would do the work economically is one which needs discussion to bring out the actual conditions from the viewpoint of public officials, engineers and contractors, and this article was written primarily as a basis for such discussion by one who believes that force account is going to be gradually adopted as the most economical and satisfactory method of constructing public works.

Conditions Favoring Day Labor Not Generally Possible

BY PAUL G. BROWN

Contractor and Engineer, New York, N. Y.

SOME YEARS ago I did a large amount of tunnel construction for the city of Chicago by direct employment of labor and made very good progress and remarkably low costs so that I feel I can come to this discussion with an open mind. I was so puffed up with the success of this undertaking that when the editor of *Engineering Record* asked me to write an article describing the work accomplished, I gratuitously recommended that all municipal work be done by that method. Since that time I have been continuously engaged in construction work on the contractor's side and have come to the conclusion that only in very exceptional cases can public works of any kind be economically carried out by force account methods.

The Panama Canal was a matter of national pride and the government was able to secure first Mr. Wallace and then Mr. Stevens, engineers of great ability, both to plan and to organize, yet I have not the slightest doubt that any one of a half dozen of the then contractors would have organized to do the work more quickly and carried it to a finish in less time and at lower cost. I also think that a contractor on the job would have had the foresight to execute the work in such a manner that the closing of the canal after its opening would have been avoided.

The wisdom of the execution of the projects of the U. S. Reclamation Service by force account is being much discussed in the daily press at present.

The Miami District was very fortunate in securing Charles Locher to head this project. Few such men would ever be available for force account jobs.

We have just read of 1,600,000 men operating as well as maintaining the railroads with their present large volume of traffic, while 2,000,000 men under the government failed both in operation and in maintenance.

In Italy where the government is taking a hand at operation, the total receipts of the railroads in the past few months were not equal to the payrolls.

The municipal operation of the Detroit street railways is a startling object lesson to those who wish to learn.

My discussion will be limited to Mr. Holleran's five conditions "which might be considered favorable to the adoption of the force account method."

(1) The minor politician only stays in public life for such a period as he can please his constituents—and that is only as long as he can get jobs for the lame, the halt and the blind. The pressure for jobs is always too great to withstand.

(2) The administration might be able to support itself against unjust criticism but there will always be enough criticism to condemn such a method.

(3) The proper compensation for a qualified administrator to take charge of even a modest construction

project is in excess of that usually paid to any municipal or state official, so that the chance of getting properly compensated and qualified leaders is very small.

(4) Readily possible.

(5) Most of our states and cities have civil service and other laws now enacted that would prevent the proper selection of men; as those best qualified could or would never pass examinations. These laws would also protect incompetents. The purchase of materials is so restricted by law as to be a great handicap.

Four of the five conditions assumed as necessary to successful conduct of force account work being found absent, further discussion would be fruitless.

* * *

Politics Hampers Force Account Construction

BY CHARLES H. PAUL

Chief Engineer, Miami Conservancy District, Dayton, Ohio

OF THE FIVE conditions favorable to force account methods, the vital one is: "*Assurance that the organization would be entirely unhampered by political interference.*" With this assurance, one of the biggest handicaps to force account construction is out of the way.

Under present conditions of municipal politics, however, is it often that assurance can be had?

And if conditions are favorable at the inception of the work, is there a reasonable probability that they will continue so, over a period of years?

It is not safe to assume that the success of the work will be its own defense, because ordinarily public interest in routine municipal work is extremely phlegmatic. Criticism travels much farther and faster than praise. A small minority of active critics will make much more impression on the public mind than a host of satisfied observers who usually are undemonstrative and are attending to other business. The unscrupulous politician, though he may be quieted and pushed aside for a time, is never asleep. He is patient, shrewd, and accustomed to guiding public opinion. If it meets with his plans to get a hold on your municipal force account job, the chances are that in due time he will succeed.

The writer has been actively engaged in force account construction on public and semi-public work for a number of years. Two of the jobs most recently carried through on that basis were the Arrowrock Dam, for the U. S. Reclamation Service, and the flood control work for the Miami Conservancy District (Ohio). The economy of handling those jobs by force account has never been questioned and in both cases the work was finished ahead of schedule. Political influence was entirely absent in both of those organizations, due largely to the personalities and the uncompromising attitude of the men at the directive heads of the undertakings.

Such jobs as those cited, however, are in a different class from routine municipal work. You have a project of more than ordinary interest to the public, not only because of its unusual construction features, many of them almost spectacular, but because of its vital necessity from an economic standpoint. Speed and quality of work are two essentials which have first place in the public mind from the beginning. Community pride in the accomplishment of the unusual soon establishes itself. With public interest thus kept alive there is little danger of political interference. Furthermore the organization itself is tuned up to do a certain definite

job, starting fresh, with a clean slate. New associations, new surroundings, new problems, all make it easy to keep the men on their toes from the start.

Routine municipal work, on the other hand, is of a nature not to excite or hold the interest of the public, except perhaps for a short time or in a restricted locality. Political interference is much more likely to creep in and it is much harder to keep an organization keyed up to high efficiency. Municipal work of a special nature, however, like the development of a park system or a municipal light and power plant, or a water supply reservoir, may come in the first class.

It is the writer's opinion that political interference on force account construction for routine municipal work might be so hard to control as to make it inadvisable to attempt such an arrangement on a large scale or as a regular thing. Special conditions as to public sentiment, personality of leaders, labor or industrial conditions, may throw the balance the other way in certain cases. Projects of special interest, large enough to justify the expense of organization and equipment, may often be handled by force account at a considerable saving of both time and money, and without danger of getting into politics.

The other conditions mentioned by Mr. Holleran as favorable to force account construction need little comment. Not only should size of organization and adequate salaries be important considerations, but ordinarily the job should be large enough to justify the purchase, and absorb the cost, of suitable equipment. Only in unusual cases is it economical to rent equipment.

Savings from Day Labor—The advantages of force account construction under suitable conditions are many. The saving in time of getting started stands out as one of the most important. Of no less importance is the opportunity to change plans as the work proceeds in cases where the exposure of foundations, character of materials, or other considerations make such changes advisable. Many such changes have been made in force account work under the writer's direction, at a large saving in cost or time or both, which on a contract job might not have been practicable because of possible complications with contractor or surety company. The location of the Arrowrock Dam was moved several feet downstream after the exposure of bedrock, at a considerable saving in cost. A similar change at another dam of the Reclamation Service, which was being built by contract, resulted in extra work claims and a suit by the bonding company, with a final settlement which offset a large part, if not all, of the saving effected.

Changes in cost of labor and materials go where they belong in case of force account work, as do also costs of unforeseen difficulties such as floods, unfavorable weather conditions, etc. A contract bid usually covers a reasonable number of such contingencies, and the owner pays for them whether they occur or not. If they do occur, and amount to more than was anticipated, the owner usually pays in the end anyway, by way of delays, extra work claims, inferior work, or other alternative. He ought to. There is no justice in making a contractor responsible for conditions beyond his control, and little does it profit a community to secure a job at less than its legitimate cost. But on the other hand why pay for speculative contingencies which never occur? That cannot well be avoided in contract work; it is taken care of automatically by the force account method.

As to engineering, it has been the writer's practice to organize engineering and inspection just about as it would be on a contract job, measuring quantities periodically for the purpose of cost and progress records, and providing inspection in the same way, so as to assure quality of work while giving the construction forces full opportunity to concentrate on speed and economy of operations. The real saving in engineering comes from the fact that what is ordinarily classed as contractor's engineering—layout of construction plant, design of falsework, cost records, clerical work, etc., can be taken care of by the same engineering organization without additional expense. Then of course there is a profit to the job growing out of the feeling of co-partnership between engineering and construction forces, which is hard to translate into money value but is nevertheless real.

Interest Kept Up—Under "Disadvantages" Mr. Holleran mentions the danger of "letting down" on the part of the force account organization, and the lack of incentive to produce economical work. Isn't that largely a matter of personnel and conditions of operation? Published records of progress and costs, merit ratings, and perhaps a well planned bonus system, will go a long way towards keeping up the right spirit on the job. The sporting instinct in our American workman rarely fails to respond to a challenge. The job of keeping the progress line up and the cost line down, if put up to the men in the right way, brings out a surprising response, especially if night shift can be pitted against day shift, or one gang against another.

There has been no indication, in the writer's experience, that it is any harder to keep up interest on a force account job than on one done by contract. Output records are a good indication of the spirit of the job. At Arrowrock in four consecutive months 205,000 cu.yd. of concrete were placed in the dam, by three 1-yd. mixers, working 16 hours a day. In one month the output was 56,520 cu.yd., an average of better than 45 cu.yd. an hour for a month. As far as is known that is a record for that size mixer. On the Miami Conservancy work one 15-in. dredge pump put 91,500 cu.yd. of material into one of the dams during a month of 26 working days, two 10-hour shifts. At another dam two 15-in. pumps, one working only part time, pumped 180,000 cu.yd. into the dam. Over a million cu.yd. of hydraulic fill per year was placed in the latter dam in two successive years of nine working months each. One dragline machine equipped with an 85-ft. boom and 4½-cu.yd. bucket loaded 9,900 12-yd. cars with gravel, in one month of 26 days, two 10-hour shifts, an average of better than 190 cars per shift for a month. Those may or may not be world's records, but there certainly wasn't any loafing on the jobs where they were made.

Some effort has to be made of course to keep up enthusiasm on any job, whether it be force account or contract, but there are any number of ways of doing it, effective for foremen, superintendents and general managers as well as the men themselves. On the other hand, concern over financial difficulties on contract work, while a stimulus up to a certain point, may often become a real detriment to the job if it gets to be too serious.

Apathy on the part of the administrative officer himself is just as likely to be reflected in injudicious awards or indulgence to favored contractors as in lax attention

to force account work. Here again the special job stands out in a different class from that of routine operations.

Must Have Large Scale Work—Ordinarily force account methods can not well be tried out on a small scale, as has been said, but in some cases that has been done, and with marked success. The city of Dayton, Ohio, is now resurfacing with asphalt a number of streets by the force account method. As to rate of progress and character of work, the plan is highly successful. Very little additional equipment was needed over and above what was already required for street maintenance. The work is well organized, and the job is going ahead rapidly, and with very little inconvenience to the traveling public. It is understood that cost figures are considerably lower than have been obtained from recent bidding.

All of which goes to show that each job should be studied by itself, and whether or not it should be handled by force account depends largely upon the conditions surrounding that particular job.

Even on a force account job there are often many small incidental jobs which are better handled by contract, just as on a contract job parts of the work may be sublet to advantage. An organization built up to handle big work is not usually fixed to handle small isolated jobs economically. A small contractor with an outfit under his personal control can often take care of such jobs much better and at lower cost, because of close personal supervision and low overhead. Also, when a relatively small job requires special equipment or special methods, it is often possible to find a contractor fixed to handle it more satisfactorily than the main organization can. While the work of the Miami Conservancy District was a force account job, still there were many parts of it handled in this way by small contractors, with most satisfactory results. To overcome some of the disadvantages of straight unit price contracts, a cost-plus-variable-fee contract was worked out, which is virtually a compromise between force account and ordinary contract methods, combining some of the best features of both. A detailed description of that plan is given in Part IX of the *Technical Reports*, published by the Miami Conservancy District.

We know that force account methods, on a large scale, can be used to advantage and with economy, when conditions are favorable or suitable. Often there are conditions which are not suitable, as has been outlined in the original paper and in this discussion. Every job should be studied carefully before adopting force account methods to see that conditions warrant that arrangement. Because it has been conspicuously successful in some cases is no reason why it is always desirable. Generally speaking, routine municipal work, in the opinion of the writer, does not offer as attractive a field as do special jobs of greater public interest.

Canals Tonnage Shows Slight Increase

The Sault Ste. Marie canals carried during September 1,700,624 more tons than in September of 1922. Iron ore shipments increased from 6,658,148 to 9,480,891 tons; wheat fell off 14,885,743 bu., and other grains 7,366,433 bu. Total freight carried over the Welland canal last September amounted to 566,452 tons, as compared with 520,779 tons in September a year ago. On the St. Lawrence canal during September Canadian steam vessels showed an increase of 124,920 net tons, and United States vessels a decrease of 60,371 tons.

Timber Preservation in 1922

WOOD preservation in the United States during 1922 amounted to 166,620,347 cu.ft. of wood, or 20 per cent less than during 1921, according to a statistical report made by R. K. Helphenstine, Jr., U. S. Forest Service, and published in the annual "Proceedings" of the American Wood Preservers Association. The principal cause given for the smaller output is the reduced use of treated ties owing to the need of strict financial economies on the part of the railways, together with the coal shortage, the car shortage and the railroad strike. There was a volume reduction of about 25 per cent in ties treated and 36 per cent in wood blocks treated, but on the other hand there was an increase of 65 per cent in piles, poles, cross arms, construction timbers and miscellaneous material. In total there were 123,949,422 cu.ft. of ties, 3,947,551 cu.ft. of wood blocks and 17,008 cu.ft. of the third class.

The total consumption of creosote, paving oil and miscellaneous preservatives was greater than in 1921. But the consumption of zinc-chloride was less, owing probably to the fact that it had been used temporarily by several plants on account of the creosote shortage consequent upon the war.

Railroad ties represent by far the greatest amount of wood treated, constituting 75 per cent or more of the total annual treatment. Of the 41,316,474 ties treated in 1922 the preservatives and their amounts per cubic foot were as follows: Creosote, 20,208,362 ties, 6.59 lb.; zinc chloride, 17,418,107 ties, 0.50 lb.; zinc emulsion, 3,681,971 ties, 0.50 lb. zinc and 2.74 lb. creosote; miscellaneous preservatives, 8,040 ties. About 97.5 per cent of the ties were for steam railroads, and of these 4,841,464 ties were adzed and bored before treatment, 1,269,117 were adzed only and 178,594 were bored only. As to the woods used, 40.9 per cent of all treated ties were oaks (including all varieties); 23.1 per cent yellow pine; douglas fir, 9.4; beech, 6.8; western pine, 3.9; maple, 3.6; birch, 3.5; gum, 3.3; tamarack, 1.5; hemlock, 1.4; elm, 0.6; others, 2 per cent.

There were 144 timber treating plants in 1922, of which 128 were in operation; 89 were commercial plants, 30 railroad plants and 25 owned by mining and power companies or public utilities. Twelve new plants were built during the year and three plants were abandoned.

Domestic oil consumed (made from coal tar and water gas tar) amounted to 50,859,151 gal., as compared with 35,462,238 gal. of foreign or imported oil, or 59 and 41 per cent respectively. The consumption of paving oil was 1,414,682 gal. Miscellaneous preservatives amounted to 2,176,843 gal., showing an increase which is attributed principally to the use of petroleum oil and coke-oven tar to dilute creosote oil. The consumption of zinc chloride was 29,863,639 lb., or about 41 per cent less than the 51,375,360 lb. in 1921, which was the highest annual figure on record.

Waterproofing of Mellon Bank Foundation

Hydrolithic waterproofing was used in the foundation and basement of the Mellon Bank, described in our issue of Nov. 1, p. 714, in place of Cow Bay waterproofing cement mortar mentioned in the article. Cow Bay waterproofing was called for in the specifications, but the contract for the waterproofing was awarded to the Hydrolithic Waterproofing Co., of New York, for application of the material first mentioned.

Winter Building Is Practicable and Profitable

Speakers Before New York Building Congress Claim Lower Prices and Higher Output in Winter

"BUILD in winter and keep the architect, the builder, the subcontractor, and labor busy. It will better balance up the industry." These statements by John W. Lowry, Jr., struck the keynote of the winter construction conference held Nov. 21 by the New York Building Congress. "With an expenditure of \$3,863 for protection of workers and materials and for heating," continued Mr. Lowry, "there was a saving of \$87,710 on a job which cost \$750,000." Giving details he said:

Considering the bricklayer production in the summer of 1922 as 100 per cent, in the erection of this job during the winter of 1922-23, the bricklayer production was 109 per cent. This last summer, the bricklayer production was 91 per cent. On this job, carried on during the winter, therefore, I produced 18½ per cent more brick per day per man than I was able this last summer.

Bricklayers got \$10 a day. The payroll was \$28,150. If the work had been conducted this last summer of 1923, the dropping off in production, or in efficiency, if you so choose to call it, would have added \$5,360 to the cost of bricklayers alone. If the bonus of \$4 be included, that is \$14 per man per day, the bonus would have cost \$11,260 more. In other words, the brickwork on this job would have cost \$16,890 in addition to the \$28,150 actually paid. The payroll for bricklayers, carpenters, labor and engineers amounted to \$130,667. If the work had been done last summer, rather than the previous winter, the dropping off in production and the bonus award would have added \$25,680.

In addition to the saving in labor on this job, the saving on materials and in sub-contracts amounted to \$16,030 compared with prices in the summer of 1922. Between labor and the purchase of materials and sub-contracts, then, there was a saving of \$87,710 on building work which cost \$750,000. To offset this sum, the expenditures for winter construction were: Temporary protection to labor and material, \$871; tarpaulins cost \$667, with a salvage of \$442, net cost \$225; temporary heat, \$668; salamanders, \$302; coke, \$304; boiler attendants, \$1,036; coal for boiler heating \$150; temporary lighting, labor and service, \$196, and snow clearing, \$111. These are a total of \$3,863, or about one-half of one per cent of the total cost of the job.

That working with concrete during the cold season is practical from every standpoint was explained by W. J. Barney, president of the Barney-Ahlers Construction Co. He said:

From our files, I have taken three typical contracts, and the amounts given under the total contract column are practically for the reinforced-concrete structure, the enclosing walls, sash and roof, in other words, for that part of the building which requires protection from winter winds, freezing and cold in the course of construction. Once the building is enclosed, the matter of heating for the finishing trades is comparatively simple, especially if the permanent heating plant has promptly followed up the structural work. In a general way, about 5 per cent of the contract represents the cost for winter protection.

Total Contract	Time of Protection	Cost of Protection	Percentage Costs
\$263,000	Dec-Jan.	\$13,000	5
180,000	Dec-Jan.	8,800	4½
95,000	Jan-Feb.	6,300	6½

This, however, does not represent the true cost of winter construction, as the cost of this winter protection, especially

under present conditions of the labor and material markets, is more than offset by the lower cost of materials during the winter, the absence of bonuses paid to mechanics and the greater efficiency of mechanics under conditions when work is not so plentiful.

Take the past year for example, we find that lumber purchased in June would cost approximately 10 per cent less if purchased in November. We find that roofers, or 3-in. boards, which enter so largely into form construction, are purchased for \$1 per thousand less in November than in August. We find that common brick entering into the curtain walls is purchased for \$3 less per thousand in November than in August. We find that reinforcing steel is purchased for 7c. per hundred pounds less in November than in August, and we know that cement has had its seasonal drop.

Moreover, it is a matter of common record that during the past summer bricklayers were paid \$14, \$16 and \$18 and even as high as \$20 a day; that cement finishers were paid as high as \$15 or day; that carpenters frequently received bonuses of from \$2 to \$3 per day, that all labor was scarce, difficult to obtain and very naturally not working at full efficiency under such conditions. We know that it is now possible to obtain practically all laborers and skilled mechanics, especially in reinforced-concrete construction, at the established union rates, and that, moreover, the men are anxious and willing to work efficiently and skillfully and have interest in holding their positions.

A still more vital factor to be weighed is the selling psychology of the general contractor which always follows a definite seasonal trend. In the spring and summer when work is plentiful, the general contractor and the special contractor will invariably place upon his work a considerably larger margin of profit and contingency, justifiably so against the skyrocketing of summer costs. In the fall when work begins to become scarce and the contractor is confronted with the problem of holding his organization together during the winter months, he will invariably lower his percentage of profit and take work on a closer basis as to contingencies, appreciating that he will be able to manage, control and direct his work far more efficiently during the winter months than in the summer; and, consequently, can operate safely upon a closer margin than when he does not know from week to week, as during the summer months, whether mechanics' wages will increase two, four, six or eight dollars per day.

I have had our estimating department take from their files typical estimates and, using these various factors, the same building would have been estimated by us in August at \$208,000 and today for winter construction at \$203,000, showing a saving to the owner of at least \$5,000 or 2½ per cent, this including all cost of winter protection. Therefore, under present labor and material conditions, it is certainly conservative to say that winter construction costs no more than summer work.

Railway Statistics for 1922

A preliminary abstract of statistics of common carriers for the calendar year 1922, issued by the Interstate Commerce Commission, gives the following particulars of first-class railroads, exclusive of switching and terminal lines:

Miles of road	234,986
Miles of second track	32,321
Miles of main track, sidings and yards	332,101
Operating revenue	\$5,559,092,708
Operating expenses	4,414,522,334
Net revenue from operation	1,144,570,374
Gross income	1,191,674,595
Net income	371,256,333
Steam locomotives	64,139
Other locomotives	373
Freight cars	2,293,402
Passenger cars	54,354
Company service cars	105,610
Tires laid in replacement	86,639,547
Tires laid in additions and extensions	4,110,213
Rails laid in replacement, tons	2,618,566
Rails laid in additions, tons	374,746
Track, in miles	197,785
Total freight carried, tons	1,340,954,570

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Engineers May Be Eligible for Scholarships

Sir—Since writing the memorandum mentioned in your editorial of Nov. 29, 1923, p. 873, which expressed the then official attitude of the Department of Education of New York in regard to scholarships in engineering courses, we have had a conference with certain deans of engineering schools and we have agreed upon an amendment to be submitted to the legislature next winter which will, I am very sure, be entirely satisfactory not only to all the engineering schools of the country but to the engineers as well. By this amendment, if it shall be enacted into law, applicants for scholarships pursuing engineering courses will be eligible to receive such scholarships. I am glad to give you this information which you are at liberty to use as a postscript to your criticism of the department.

Albany, N. Y., AUGUSTUS S. DOWNING,
Nov. 30, 1923, Directing Professional Education,
State Department of Education.

Why the Garden City Project Failed

Sir—Your articles on the trail of the truth about reclamation have been of more than ordinary interest to me. I especially enjoyed reading the article by F. H. Newell on Origin, Problems and Achievements of Federal Land Reclamation, but I cannot agree with Dr. Newell when, with reference to the Reclamation Service project in Kansas, he says, "this project did not succeed largely because the climate was not sufficiently arid."

The Garden City project was planned to pump groundwater to supplement the river supply for the Farmers' Ditch, a ditch which had been in operation since about 1880. Much information regarding this project was given in the 1905 report of the Reclamation Service. The proposed plant was to "recover an average of 100 sec.-ft. of groundwater during the irrigation season of five months, to be delivered into the Farmers' Ditch about one mile northeast of its headgates."

The cost of construction was to be about \$30 per acre, based on the 8,600 acres then under that ditch. Charges were to be in two parts, the first a fixed charge of approximately 75c. for each acre of land under the project, whether the owner used water or not, the second charge for distributed water, the cost of which, based upon a total of 25,000 acre-ft. delivered to the water users, would be 77c. per acre-foot. On this basis a water users' association was organized, and on Sept. 14, 1905, an allotment of \$258,000 was made for the construction of this project.

Before the project was completed and put in operation the construction charge was raised to \$37.50 per acre. The charge for maintenance and operation was raised to a minimum of \$2.75 whether water was used or not; 2 acre-ft. per acre was to be furnished. In addition to these charges it was required that the water users operate and maintain their distributing system "at their own expense."

The delivery of water was begun in 1908 with 10 of the 23 pumping units installed. The others were utilized as they were installed in June and July, but the amount of water pumped that year is not given in the annual report. In 1909 the plant was in operation 96 days and 7 hours, and pumped a total of but 7,555 acre-ft. of water. This was at an average rate of a little less than 40 sec.-ft., or less than 40 per cent of the expected amount. Furthermore, running this small amount of clear water in a ditch having a capacity of 200 sec.-ft., which the Farmers' Ditch had, resulted in an unusually large ditch loss, and a wholly inadequate quantity of water reached the land. Upon the

failure of the Service to deliver the expected amount of water, the farmers refused to pay the assessments and the project was abandoned.

If, as Dr. Newell says, the project did not succeed because the climate was not sufficiently arid, it was only because the climate was not sufficiently arid to compel the farmers to pay an almost prohibitive price for an unsatisfactory amount of water to supplement their river supply, and not because they did not appreciate the value of water. As an irrigation engineer I have been in close touch with irrigation at Garden City for more than ten years, and personally know many of the farmers under the Farmers' Ditch. They have consistently utilized all the water available, and if a dependable supplementary supply could be developed at a reasonable cost they would gladly avail themselves of it. Of the five ditches in operation in the Garden City district in 1905, all are well maintained and are in operation at this time. In 1922 they diverted and used 67,800 acre-ft. of water out of a total of 107,500 crossing the state line into Kansas during the water year Oct. 1, 1921, to Sept. 30, 1922.

Furthermore, the failure of the Reclamation Service to develop a satisfactory water supply from wells did not demonstrate that it was not practical to pump groundwater. Within recent years about 20,000 acres in that district have been brought under irrigation by private pumping plants on individual farms. These plants cost from \$2,000 to \$2,500 for units having a capacity of 3 or 4 sec.-ft., which is large enough for 160 acres. This is a construction charge ranging from \$12.50 to \$15 an acre. Operation costs are about \$2 an acre annually with electricity, which can be obtained at 4c. per kilowatt-hour.

The Garden City project failed partly because the Service was unable to construct and operate the project within the figure fixed in the original agreements, but in larger part because of the fact that they failed to deliver the water for which charge was being made. The increase in both cost of construction and charge for maintenance and operation had caused some dissatisfaction among the water users, but this could have been overcome had it not been for the fact that the Service was unable to deliver the water for which charge was made.

Topeka, Kan., GEORGE S. KNAPP,
Nov. 6, 1923. State Irrigation Commissioner.

Traffic Congestion Costs

Sir—In connection with your editorial, "Capitalizing Traffic Congestion Cost," in the issue of Nov. 8, p. 747, the following may be of interest.

The cost, merely in terms of gasoline consumption, of starting from a stop the cars in a heavy traffic stream is not generally realized. About 42,000 ft.-lb. of energy are required to accelerate a ton of car weight from a stop to a speed of 25 m.p.h. One gallon of gasoline will furnish approximately 4,200,000 ft.-lb. of effective energy when burned in the average motor vehicle now in use. In other words one hundredth of a gallon of gasoline is consumed in accelerating every ton of car weight from a stop to a speed of 25 m.p.h.

If 10,000,000 cars of an average weight of 1½ tons move through the traffic stops of Fifth Avenue each year and make on the average five stops per car, approximately 750,000 gal. of gasoline will be consumed in accelerating the vehicles in the traffic stream. At a gasoline cost of 20c. a gallon the driving public spends about \$150,000 per year for the fuel required to bring the cars up to driving speed after traffic stops, or the interest on an investment of \$3,000,000. Were each car stopped and the engine idled for five minutes during its trip on the Avenue, the annual expenditure for gasoline so consumed would be about \$50,000, or an additional capitalized cost of \$1,000,000. Although I do not have the exact number of traffic-control stops on Fifth Avenue per year, the above figures at least indicate the magnitude of the annual cost to the driving public of two of the items of the cost of car operation through traffic stops.

Washington, D. C., Nov. 27, 1923. WILLIAM S. JAMES.

Temperature of Irrigation Water

Sir—Plans are being made for a large hydro-electric development in Japan where the river water is used for the irrigation of rice. The rice growers are fearful that the temperature of the water drawn from the storage reservoir to be constructed will be lower than that at present drawn directly from the river.

The plans as submitted for the government permit provide for a dam to raise the water surface about 210 ft. with a storage of about 20,000 acre-ft. The minimum flow of the river is about 1,000 sec.-ft. The intake as planned provides for a draw down of 50 ft., so as to give a regulated flow of about 1,500 sec.-ft. The reservoir will, however, be full during the rice growing season.

The rice growers' associations insist that the plans be changed to provide for drawing the water from near the surface of the reservoir unless evidence is submitted to show that water drawn 50 ft. below the surface of the reservoir will have a temperature as high as that of the river water under existing conditions.

The only printed information which we have found on this subject is contained in the following papers in the Transactions of the American Society of Civil Engineers: "Temperature of Water at Various Depths in Lakes and Oceans," by Hamilton Smith, Jr., Vol. 13, p. 73; and "The Temperature of Lakes," Desmond FitzGerald, Vol. 34, p. 221.

These papers show that in reservoirs during the summer months lower temperatures increase with depth to certain limits, but no information has been found to show the temperature of water at various depths, as compared with the temperature of the running water in the river.

Any information which can be furnished on this subject will be much appreciated.

E. C. MACY,

Manager for Japan for Stone & Webster, Inc.
Boston, Mass., Nov. 5, 1923.

Contract Bond Reform

Sir—I was interested in the editorial in *Engineering News-Record*, Nov. 8, p. 748, entitled "Contract Bond Reform."

I heartily agree that 11 per cent is too high a rate for responsible contractors to pay, and that this rate is due to the "unwise risks which are constantly being taken."

In this connection, I am enclosing extracts taken from a letter I recently wrote to a large bonding company, which may be of interest.

It is probable if negotiable securities are accepted in lieu of bonds, the bonding companies will be compelled to select their risks with more care, and reduce their rates. Of course a material reduction in rates will be possible if the bad risks are eliminated.

FRANK M. WEAKLEY,

Norfolk, Va., Nov. 10, 1923. Civil Engineer.

[The discussion inclosed by Mr. Weakley follows.—EDITOR]

Some years ago I was bonded on a building contract. The standard rate at that time was 1 per cent but I paid 0.8 per cent because my business was "preferred."

The agent informed me that he personally investigates his patrons and prospective patrons, and upon his recommendation they were given a special rate.

In checking up on contractors who have gone bankrupt, leaving the bondsmen to finish the work at a loss, I find that in most cases the risk could have been ascertained by the bondsmen by a proper careful investigation.

You will note that a large proportion of the bankruptcies are cases where the contractors have been in business for a number of years.

The manner in which a business is being operated can be learned in a number of ways, apparent to me, or to anyone else sufficiently interested.

If a business is being poorly managed, it is usually only a question of time until it goes broke, causing a loss to the bondsmen.

I had difficulty in securing my first bond; after that it was easy.

The biggest losses to bonding companies are from contractors who have been operating for a number of years, sufficiently long for anyone interested to ascertain how they were handling their work.

A contractor who gives personal attention to his work, who pays his bills promptly, handles his workmen intelligently, treats his sub-contractors fairly, and secures his work at reasonable prices will nearly always succeed. He is a good risk.

The man who does the opposite is a bad risk, even though he has to his credit a number of completed contracts.

Why then, do not the bonding companies establish credit and investigation offices in the larger cities which will check up on their risks and prospective patrons?

These offices can get information as to how the contracts are being executed, the payments made on material and labor, payments to sub-contractors, and, in fact, everything regarding the way the contractors are handling their work and finances.

Such an office should be independent of the agent who writes the business, just as the fire insurance offices which fix rates are independent of the agents who write the fire policies.

As a practical business man and builder, I can see no good reason why a careful check on contractors' work cannot reduce losses considerably.

I have occasionally been surprised by seeing contractors of questionable reputation and ability secure bonds from large companies who later on had to make good on the failures that were to be expected.

National Construction Week Advocated

Sir—I note the editorial in *Engineering News-Record*, Nov. 1, 1923, p. 704, relative to the possibility of a Construction Show.

I am sending you a little article I prepared some months ago along the same lines, which may interest you. The possibilities are immense, and while perhaps Atlantic City is the only town with sufficient hotels and display facilities to accommodate a real Construction Week, I think a biennial or triennial meeting can gradually be brought about, and it would certainly put the construction industry on the map of the United States. Alternate years, each national association could move about the country as its best interests might require, and take the mountain to Mohammed through America, which is perhaps equally essential.

A. P. GREENSFELDER,

Secretary, Fruin-Colnon Construction Co.

St. Louis, Mo., Nov. 15, 1923.

[The following extract from the article forwarded by Mr. Greensfelder contains the substance of his proposal.—EDITOR.]

The idea of a national construction week is that the National Federation of Construction Industries could arrange the first two days of that week, taking up the broad construction problems of interest to the entire industry, such as transportation, finance, standardization, co-operation, etc., referring the problems back to each group for the co-operation of their organizations. On the following three days of that week, it is hoped that the various groups, such as the Associated General Contractors of America, the American Institute of Architects, the Builders' Exchanges, the recently formed federation of engineering societies, the Material Dealers' Association and a lot of other national associations, could hold their individual conventions in different hotels simultaneously in the same city. On the last day of the week the executives of the various national associations could again gather together under the leadership of the National Federation of Construction Industries, reporting the action of their various organizations and establishing a uniform policy of action for the coming year.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

At the Recent Convention of the City Manager's Association in Washington, D. C., Montreal was chosen as the next meeting place and George W. Thompson, Westmount, Que., as first vice-president. The new president is Earl C. Elliott, Wichita, Kansas.

For the Statue of Colonel William F. Cody (Buffalo Bill) Mrs. Harry Payne Whitney, sculptress, has engaged Russell Kimball, engineer, of Casper and Cody, Wyo., to take charge of the erection of the base. The base will be of red granite quarried from the Shoshone canyon and the estimated cost is \$40,000. The statue when completed will be placed near the city of Cody, Wyo.

The First National Conference on Immigration is to be held in New York City, at the Hotel Astor, Dec. 13 and 14 the call having been issued by the National Industrial Conference Board, New York. An attendance of 2,000 of the nation's leading industrialists, public officials, leaders in business and trade organizations, and authorities on social service is expected. All sessions will be public.

Hiressi Yamamoto, Marine Superintendent of the Japanese Government Rys., Tokyo, Japan, has arrived in Canada to study the car-ferry system which connects Prince Edward Island with the mainland. It is the intention of the Japanese Government to connect the southern island of Yesso with the larger one of Honbu by means of a car ferry over a strait about 60 miles broad, conditions being somewhat similar to those of the Northumberland Strait.

Winnipeg, Manitoba, Has Adopted a by-law for the issue of debenture bonds to the amount of \$550,000 for the purpose of establishing a central district steam heat producing and distributing plant in connection with the city hydro-electric standby plant. The total cost will be \$875,000, leaving a balance of \$325,000 to be transferred from the capital account of the hydro-electric system. The work will be proceeded with as soon as enough heating contracts have been signed to insure the success of the system.

Application for a License Covering the remainder of its projects on the Tallapoosa River has been made by the Alabama Power Co. The company has recently completed the survey of the entire stream by means of aerial photography and has found that the estimated storage capacity of the upper region has been over-estimated. Consequently it proposes to increase the height of the Cherokee Bluff dam from 105 to 150 ft. The five additional dams are to be constructed above the Cherokee Bluff dam, which will have a combined head of 306 ft. and an installed horsepower of 114,000.

Knickerbocker Theater Co. Wins Three Damage Suits

The Knickerbocker Theater Co., Washington, D. C., has been exonerated of civil liability in three of half a hundred cases brought against it as a result of the collapse of the theater's roof Jan. 28, 1922. The three suits, the first civil cases to be decided, were for \$10,000 damages each, and were based on the death of two patrons and the injury of a third. Attorneys for the plaintiffs will seek a new trial, and if that is not granted, intend taking the cases to the Court of Appeals.

Japan To Spend \$525,000,000

Conditions in Japan are gradually becoming settled. Military law has been discontinued and sufficient temporary structures have been provided to care for all who were without shelter, says a cable received by the Far Eastern Division of the Department of Commerce from its Tokyo representative. It is unofficially estimated that reconstruction expenditures during the first five years will reach only \$525,000,000, of which amount \$375,000,000 will be spent in Tokyo and \$150,000,000 in Yokohama, indicating that either the damage caused by the earthquake was not as great as it appeared, or that the program of reconstruction will be carried out over a long period of years.

International Board Disallows Rio Grande Claim

Fred K. Nielsen, agent for the United States before the American and British Claims Arbitral Tribunal, has informed the Department of State that the claim of the British Government for £755,100 with interest against the government of the United States, known as the Rio Grande Claim, has been dismissed by the arbitral tribunal which is now sitting in London. The claim is based on an alleged interference by the Government of the United States with real property rights at Elephant Butte, Sierra County, New Mexico, of an English company called the Rio Grande Irrigation and Land Co., Ltd., which about 1896 had taken steps to construct a dam in the Rio Grande River at Elephant Butte. Pursuant to acts of Congress approved Feb. 25, 1905 and March 4, 1907, respectively, a dam was constructed at Eagle, New Mexico, a short distance below Elephant Butte, as a result of which the site of the dam which the Rio Grande Irrigation and Land Co., Ltd. had proposed to construct at Elephant Butte was submerged. The company's dam had not proceeded beyond the initial stages (it is said that the small beginning had been practically obliterated by floods, etc.) and the time limit within which the law required completion of the work had meanwhile expired.

Huge Appropriation Asked for More Western Reclamation

An appropriation of \$250,000,000 by Congress for Western reclamation is demanded in a resolution passed by the Western States Reclamation Association in its third conference, held at Salt Lake City, Nov. 18-20. The association also voted thanks to Secretary of the Interior Hubert Work and to the Reclamation Commissioner D. W. Davis for their work in dealing with reclamation problems. The claims of the South to federal reclamation expenditures were recognized in a resolution assuring the South that the West wishes to co-operate with it.

Several principles of future reclamation policy were advocated in formal resolutions. They include "completion" of existing projects, legislation to give the government a percentage of the increase in value of land when sold prior to full payment of the government charges, formation of interstate agreements on interstate water problems, and international agreements on international water problems.

R. E. Shepherd, Jerome, Idaho, was elected president, and W. L. Boise, Portland, Ore., vice-president. The executive committee includes: R. E. Caldwell, Utah; W. G. Wendsen, Idaho; W. E. Meacham, Oregon; C. Pease, Texas; J. M. French, New Mexico; D. A. Scott, Washington; William Wisener, Arizona; F. L. Lucas, Colorado; A. Lindley, California, and R. A. Smith, Nebraska.

Work Favors Department of Public Works

Washington Correspondence

Secretary of the Interior Work states that he is ready and anxious to co-operate in the effort looking to the establishment of a major division of public works in his department. Secretary Work expressed this determination last week to L. W. Wallace, the executive secretary of the Federated American Engineering Societies, whom he called into special conference on this subject.

Secretary Work told Mr. Wallace that he is in entire sympathy with the Brown plan for reorganizing the Department of the Interior. That plan provides for the division of the Department into two major branches, one to deal with public works and the other with matters of the public domain. The public works branch is to be under the immediate direction of an assistant secretary, who is to be an engineer. Secretary Work went so far as to suggest to Mr. Wallace that the engineers begin thinking of a man who would be qualified to fill that position.

In his conversation with Mr. Wallace, Secretary Work made the point that it would be wise to provide for the use of Army engineers in connection with the public works program. He expressed the opinion that Congress would not approve of the plan unless this were done.

Ohio Filter Operators Discuss Problems

Practically Every Plant in State Represented—Sand, Chlorine, Iodine and Carbonation

Engineering News-Record Staff Report

All but two of the sixty-five water purification plants in Ohio were represented at the third annual conference of operators, Nov. 21 to 24, at Columbus. Probably no other state has so many purification plants under laboratory control, for even the smallest plants have a laboratory for "minimum" determinations, each supervised by a technically-trained operator of a larger plant, who may have as many as five plants to which he gives attention and for which he is responsible to the State Board of Health which must approve his employment.

Besides the dozen papers on filtration, water softening and carbonization, the "tricks of the trade," or original features of plant operation, were described. A joint session on iodine and goiter was held with the county district commissioners of Ohio. The unanimous opinion seemed to be that medication with iodine in the water was wasteful (only 0.4 per cent used) and much more expensive than individual treatment. A day was used to visit the softening plants at Newark, where an 8-m.g.d. plant under construction has a baffled mixer, and at Delaware, where mechanical mixing is used in the 2-m.g.d. plant, completed last year.

CARBONATOR EXPERIENCE

Experience with carbonators at the Defiance plant was given by H. T. Campion, superintendent, who stated that the filter plates for distribution of the CO₂ had been replaced by perforated pipes with satisfactory results. Sand growth has been prevented with 1 to 10 p.p.m. of CO₂ in the effluent. C. P. Hoover, chairman of the conference and chief chemist, Columbus, described a carbonator recommended for Newark and Columbus. Flue gas, scrubbed to free it from CO and water, is blown through porous concrete blocks, the gas being distributed through the bottom of the blocks by a perforated pipe. Ordinarily any steam-producing pumping station furnishes double the amount of CO₂ necessary for the carbonation process.

F. E. Sheehan, superintendent, Portsmouth, has found that a secondary application of coagulant midway in the 8-hour detention period reduces his alum dosage and gives higher efficiencies, particularly as shown by the B. coli index. Progress being made by the U. S. Public Health Service in the study of efficiency limitations of water purification processes, was outlined by H. W. Streeter, sanitary engineer. A 0.16-m.g.d. experimental filter has been installed at Cincinnati and a survey is under way of sixteen plants from which monthly reports are received.

Electrolytic action between brasses of different composition in the East Liverpool filter strainers, said D. H. Rupp, was partly responsible for underdrain troubles which finally resulted in re-vamping the underdrains. Strainers were found plugged with concrete and oakum. In some cases plugs were found in lieu of strainers. Tons of sand were taken from the false bot-

Chinese Engineer Prominent in Flood Protection Work

Among China's prominent engineers is S. W. Law, formerly director of the Yellow River Bureau in Shantung from 1918 to 1922. He is

a native of Shantung, was educated in Tientsin, China, where he studied engineering; has followed railroad engineering for twenty-five years. He has had active practice in railway location, construction, and maintenance on several of

the principal roads of China including the Shanghai-Hangchow, Tientsin-Pukow, Peking-Mukden, and Chinese Eastern. In 1918 he was put in charge of the work of the Yellow River Bureau where he remained until his appointment as Vice-Minister of Communications at Peking in the summer of 1922.

Accept Principle of Arbitration for Standard Contracts

Acceptance of the principle of arbitration by the representatives of the American Railway Engineering Association and a reconsideration of certain other contract principles which pave the way for a general agreement were the outstanding accomplishment of the Joint Conference on Standard Construction Contracts at its meeting in Washington, Nov. 19.

The railway engineers submitted a detailed criticism of the documents previously formulated with which they were not in full accord and those matters which could not be immediately agreed upon at the meeting were referred to a sub-committee which will report about Dec. 10. The sub-committee is instructed to reach a basis for universal agreement on each of the contract provisions referred to it, redrafting these provisions if necessary and submitting its recommendations to the conference for approval.

As a result of discussions in the past year the sentiment among all of the representatives actively participating in the conference has crystallized into agreement upon an arbitration clause, with the exception of the National Association of Builders' Exchanges which has not yet rendered a definite report. There now appears little doubt that within the next few months unanimous agreement will be reached in the conference upon both the building and the railroad documents.

Associations represented on the Joint Conference are: American Association of State Highway Officials, American Institute of Architects, American Railway Engineering Association, American Society of Civil Engineers, American Water Works Association, Associated General Contractors of America, Federated American Engineering Societies, National Association of Builders' Exchanges and the Western Society of Engineers

tom. A control valve did not work and was found installed backwards.

The newly elected officers are: Chairman, Clarence Bahlman; vice-chairman, W. I. Van Arnum; secretary, E. E. Smith.

To Start \$12,000,000 Water-Works Extensions at St. Louis

The sale before Feb. 1, 1924, of \$2,000,000 of the \$12,000,000 water bond issue voted by the people last February has been authorized by the St. Louis Board of Estimate and Apportionment, in accordance with the program of E. E. Wall, water commissioner. The money will be used for the construction of railroad yards, buying rights-of-way and for constructing intakes and engine pits. In June pipe lines connecting the new water-works with the city mains and in September the construction of the new settling basins are projected. The entire program for 1924 contemplates an expenditure of \$5,590,000.

Reopening St. Louis Zoning Case Denied by Court

The Missouri Supreme Court, on Nov. 20, denied a petition of the City of St. Louis for a rehearing of its recent decision against the validity of the zoning ordinance under which the city has been acting for some three years past. The earlier decision held that the zoning ordinance was beyond any police power granted to the city by the state. The latest ruling confirms the earlier one but appears to be somewhat more specific in that it says, in part: "The ordinance before us provides for the taking of private property for a public use without compensation and without a judicial hearing. It is not a regulation that would fall within a reasonable exercise of the police power. It is confiscation, pure and simple."

Court Holds Public Utilities Act Cannot Invalidate Contract

The U. S. Supreme Court in the suit of the Superior Water, Light & Power Co. against the city of Superior, Wis., reversed the lower courts which had held for the municipality, declaring, in effect, that a state legislature is without authority to invalidate contracts between public utility corporations and political subdivisions.

The predecessor of the Superior Water, Light & Power Co. had been granted a 30-year water-supply franchise by the city of Superior. Subsequently this franchise was amended to provide either a 25-year extension or purchase of the plant by the city on a fixed basis of payment rated on income. After this amendment the water company made extensive improvements and extensions. The Wisconsin public utility act of 1907 provided that utility franchises should be indeterminate, and subsequent legislation made the indeterminate franchise mandatory.

When the franchise expired, the Superior Water, Light & Power Co. called upon the city for an extension or for purchase of the plant according to the terms of the franchise. The city refused, relying upon the state act, and started condemnation proceedings to acquire the plant by terms other than those in the franchise. The company resisted in the courts. In upholding the contentions of the company, the Supreme Court asserted that the franchise and its amendment constituted a valid contract, not subject to abrogation by the state public utilities act.

Proposes Power Development on the Headwaters of the Tennessee

The Federal Power Commission has received an application from the newly-organized Southern Appalachian Power Co., of Asheville, N. C., for a preliminary permit covering a 170 ft. dam and power house to be constructed at a point on the Hiwassee River one mile above Murphy, N. C. The dam would control the annual run-off of the river and provide a low-water flow of 1300 c.f.s. It is estimated that 50,000 hp. could be developed at this site.

The most attractive feature of the project, however, arises from the fact that 400 ft. of head can be developed in the river below Murphy, which would make possible the development of 150,000 hp. in that stretch.

The Hiwassee is a tributary of the Tennessee and has its source just over the ridge from the Tugaloo and other streams which have been so thoroughly developed on the eastern slope of the range. This new development will increase the low-water flow at Muscle Shoals by 10 per cent, and will benefit materially the Hale's Bar project of the Tennessee Electric Power Co. It will also increase the navigable capacity of the Tennessee.

Incidentally this development would drown out the dam proposed by the town of Andrews, N. C., a small municipality which is defying the Federal Power Commission. It has sold its bonds and has let contracts for its project which is seven miles above the site of the Southern Appalachian Power Co. Materials are being transported to the dam site. The district representative of the Corps of Engineers has instructions to request an injunction from the Federal Court when ground is broken.

Electrify and Elevate New York West Side Freight Line

The new plan for a general revision of the west side freight line of the New York Central on Manhattan Island, New York, noted in last week's news pages, is submitted by the railroad company in order to clear up the matter of how it is to conform with the legislation requiring the electrification of this line and at the same time eliminate all grade crossings.

The plan as now submitted is similar in many respects to the one which was submitted in 1916, but does not include the expensive subway work along Riverside Drive. As far as possible in this new project the railroad company has endeavored to keep to its present

right-of-way, thus avoiding the question of obtaining large parcels of land from the city, one of the stumbling blocks in the way of the other plan.

The present terminal at St. John Park will be abandoned and also all tracks below Canal St. The construction of the vehicular tunnel westward from Canal St. makes this change necessary. A new elevated terminal will be built north of Canal St. between Washington and West Sts. with trucking space and platforms under the tracks at street level. North of this terminal a two-track elevated structure will be built along a private right-of-way roughly parallel to Washington St., to near 14th St., where the elevated structure will be carried along 10th Ave. for three blocks on account of the new warehouses built or building in that area. From this point it will again continue in private right-of-way west of 10th Ave. to the 30th St. yards, where it will turn west to the marginal way along 12th Ave. The 30th St. yard will be an elevated structure but will have some street level tracks west of 11th Ave. to connect with the car ferry slips. From the 30th St. yard to the 60th St. yard will be a four-track elevated structure along the marginal way. At 60th St. the tracks will come down to the present level of the yard, but the east side of the yard, now occupied by stockyards, will be developed into a double-deck structure, the upper deck being for the delivery of milk and perishables. North of this yard the railroad will have five tracks at grade on the present right-of-way as far as Manhattanville, with over-crossings at 79th St. and at 96th St.

At Manhattanville the railroad will be carried over the West 125th St. valley on a six-track elevated structure to the yard, which will have two track levels. Continuing north, the tracks will come down to grade as a five-track line to Fort Washington Park and then four track to Dyckman St., where it will be elevated over the street and ferry entrance. The plans call for a small yard at this point for local business. North of Dyckman St. the track will be carried on a four-track fill to Spuyten Duyvil creek, which it will cross on a new high-level bridge having the same clearances as the other Harlem River bridges. Above the bridge, overhead connections will be made to the north and east, and some changes will be made in the location of the main line to the east to conform with the new ship canal plan.

George W. Kittredge is chief engineer for the New York Central on this work and J. M. Doorly is engineer of West Side improvements.

Construction Council Announces Apprenticeship Committee

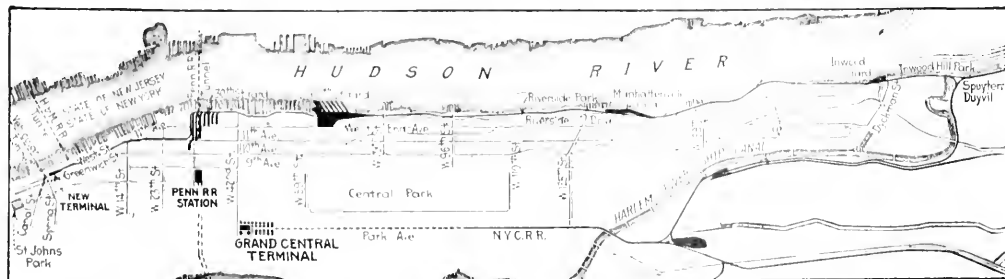

The American Construction Council has announced the personnel of the Committee on Apprenticeship, Vocational Guidance and Craftsmanship, of which F. W. Walker, of Beaver Falls, Pa., is the chairman. The committee will co-operate with employees' and employers' organizations, building congresses, and all other elements in the construction industry, and with the educational bodies, local and national, in providing for apprenticeship which will be attractive to young men and will afford the fullest means for the employment and training of efficient workers as apprentices, and will produce the skilled workmen needed in the construction industry.

Members of the committee are: James Baird, New York; Charles F. Bauder, Philadelphia, Pa.; E. L. Bowman, Evansville, Ind.; Howard L. Briggs, Cleveland; H. Whittemore Brown, Hampton, Va.; Prof. W. W. Charters, Pittsburgh; Wharton Clay, Chicago; R. L. Cooley, Milwaukee, Wis.; John W. Cowper, Buffalo, N. Y.; George Dautel, Cleveland; John Donlin, Washington, D. C.; F. L. Dykema, Grand Rapids, Mich.; Burt L. Ferner, New York; R. C. Gaskill, Atlantic City, N. J.; Frank M. Gunby, Boston; Lewis Gustafson, St. Louis, Mo.; Fred J. Hartman, Pittsburgh; Dr. L. S. Haskins, Chicago; Warner S. Hays, Philadelphia; Mr. Malcolmson, Detroit, Mich.; G. A. McGarvey, Washington, D. C.; A. H. McChan, Washington, D. C.; James S. Meade, Philadelphia; Fred F. Moran, New York; W. Stanley Parker, Boston; Thomas R. Preece, Indianapolis, Ind.; C. A. Prosser, Minneapolis, Minn.; H. H. Rosenberg, Chicago; Ralph P. Stoddard, Cleveland; M. F. Westergreen, New York; L. C. Wason, Boston; R. Winstead, Chicago; Edward L. Wertheim, New York; and J. C. Wright, Washington, D. C.

Ex-officio members are Franklin D. Roosevelt, New York; D. Knickerbocker Boyd, Philadelphia; and Dwight L. Hooper, New York.

Illinois Society Meets Jan. 9 to 11

The annual meeting of the Illinois Society of Engineers will be held Jan. 9 to 11 at the University of Illinois, Urbana-Champaign, Ill. The program is now in preparation and it is proposed to arrange a session for operators of sewage-disposal plants. H. E. Babbitt, assistant professor of sanitary engineering at the university, is president. The secretary is E. E. R. Tratman, Wheaton, Ill.

PROPOSED IMPROVEMENTS IN NEW YORK CENTRAL FREIGHT LINE ALONG THE HUDSON RIVER AT NEW YORK

Random Lines

The Interstate Commerce Commission, in order No. 13,462, finds that something about shipping "pancake flour in carload lots" is unreasonable. Shades of all the small boys on Sunday morning—Can there be that much pancake flour?

* * *

Pronounced In-jée-ner

Sir—Referring again to the popular abuse of the term "Engineer":

I am not a Latin scholar nor a delver into languages, but have observed relationships and ancestry of many of our modern English words when glancing through my "Websters Unabridged Dictionary."

I find that most words beginning with or containing *gen* or *g* n pertain to creation, production or reproduction; we have *genesis*, meaning the creation; *genitive*, pertaining to reproduction; *genius*, one of creative or inventive mind; likewise *ingenuity* the quality of ready invention, etc. Then, eureka! I find the word "ingeneer," one who contrives, a "designer," but, alas, it has (obs.) tacked onto it. This last seems to be the nearest ancestor or possibly an older disinherited brother to our modern "engineer."

The English have always had a habit of changing and modifying the spelling of words from their original. The continental European languages all spell the word, beginning with "ingen"—like the French "ingenieur."

And herein lies another inconsistency: where, in other European nouns, denoting vocation (adding *er* and *or* to a verb to denote one who), the accent is on the last syllable, the English always pronounce with the accent *before* the final *er*.

Now, according to this pedigree, an engine or a gin really means any works which have been contrived or designed by an "ingener."

In this respect a bridge or any fixed structure and all kinds of machinery, which would include sewing machines, washing machines, etc., as well as the steam engine (properly, motor), is an engine, hence why should those who operate steam motors be called engineers at all. If so called, then the woman who operates a sewing or a washing-machine is an engineer and every one is an engineer because practically everyone operates or cares for some device designed by an ingener.

The ingener, as a designer, has to precede the operator for the reason that the father precedes the son.

If the trade-and-lay-people in general persist in using the term so promiscuously, lets have that (obs.) deleted from the dictionary and have it read, "ingener, one who etc." and "engineer, (obs.) see ingener."

It is easy to say—just put the accent back in its English or American place. Now, all together,

"Ing'ener."

* * *

The Chicago Daily Tribune's booze hound (who is a sleuth and not an inebriate as in the early use of that sobriquet) has found that the prize speakers in the big lake city hides behind an office door labeled "International Council of Experimental Engineers" or something." Let's hope it's "something."

Tile Manufacturers' Association Ordered Dissolved

Washington Correspondence

Collection of trade statistics practically is limited to those which may be requested by a governmental agency, is the final decree in the case brought by the Department of Justice against the Tile Manufacturers' Credit Association. The proceeding was in the United States Court of the Southern District of Ohio. Before the decree was made final the law department of the National Association of Manufacturers urged the Department of Justice to permit the periodic collection of facts relating to capital employed, power used, wages, taxes paid, fuel consumed, machinery employed, in addition to production, sales, shipments, stocks, prices and like pertinent trade information. It was specified that all such information was to be a record of accomplished facts.

It is known that the Department of Justice gave long and careful consideration to the proposal. The significance of the decree is increased greatly by the fact that the collection of trade statistics is not made permissible after the Department's study of the proposal. It is anticipated that this decree will have a far-reaching effect upon trade associations.

In the decree the credit association is ordered dissolved, though it again may function in accordance with rules laid down by the court as an educational and research body and for the interchange of certain credit information.

Engineering Societies

Calendar

Annual Meetings

FEDERATED AMERICAN ENGINEERING SOCIETIES, Washington, D. C.; Annual Meeting, Washington, D. C., Jan. 10-11, 1924.

AMERICAN ROADBUILDERS' ASSOCIATION, New York City; Annual Convention, Chicago, Jan. 14-18, 1924.

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York City; Annual Meeting, New York, Jan. 16-18, 1924.

ASSOCIATED GENERAL CONTRACTORS OF AMERICA, Washington, D. C.; Annual Meeting, Chicago, Ill., Jan. 21-24, 1924.

ENGINEERING INSTITUTE OF CANADA, Montreal; Annual Meeting, Montreal, Jan. 22, and Ottawa, Jan. 23, 24, 1924.

AMERICAN CONCRETE INSTITUTE, Detroit, Mich.; Annual Meeting (29th anniversary), Chicago, Ill., Feb. 25-28, 1924.

The Engineers' Club of Philadelphia will hold a meeting Dec. 18 at which J. Franklin Stevens will give an address on the Pacific Islands and Japan.

The Society of Terminal Engineers, New York City, will have for discussion at its meeting Dec. 11 the subject, Cartage Practice at Inter-Terminal and Off-Track Freight Stations; the speaker will be J. F. Murphy, vice-president of

the Terminals Co., St. Louis, Mo. At the meeting of the society held Nov. 13, the following officers were elected; President, Maurice W. Williams; vice-presidents, J. Spencer Smith, William Joshua Barney, Edward Anderberg, M. A. Long, and H. C. Yost; secretary-treasurer, Charles H. Newman.

Personal Notes

R. H. SHERLOCK, formerly structural engineer with the American Bridge Co., at Toledo, Ohio, has taken up duties this fall as assistant professor of civil engineering in the college of engineering, University of Michigan.

W. M. SPANN, division engineer for the Missouri State Highway Department with headquarters in Kansas City has been promoted to engineer of construction at Jefferson City, succeeding A. C. Lingley, recently resigned. H. M. BRUSH, assistant engineer of construction, will fill the vacancy caused by Mr. Spann's promotion. A. R. AXOM, division maintenance engineer at Willoughby Springs, has been made assistant engineer of construction.

JOHN ALBERS has been appointed city engineer of Beverly Hills, Calif.

DR. PAUL WHITFIELD HORN, now president of Southwestern University, Georgetown, Texas, has been appointed president of the new Texas Technical College at Lubbock, Texas, and will assume the duties Jan. 1. For the construction of Texas Technical College, the architects are SANGUINET, STAATS & HEDRICK, of Ft. Worth with WILLIAM W. WATKINS of Houston and CRAM & FERGUSON of Boston as associates. L. W. ROBERT of Atlanta and Dallas will be consulting engineer. The college will be opened in the fall of 1924.

MALCOLM RAMSAY, Greenville, Texas, has been appointed city engineer of Temple, Texas, and will have charge of an extensive paving program.

WALTER A. SHAW, consulting engineer, Chicago, and formerly member of the Illinois Public Utility Commission, has been appointed a representative of the city of Chicago on the Board of Supervising Engineers, Chicago Traction.

EZRA B. WHITMAN, consulting engineer and a member of the Public Service Commission of Maryland, will become chairman of the commission Dec. 31, at which time the resignation of William Milnes Maloy, present chairman, will become effective.

ROBERT ISIAM RANDOLPH, secretary of the Randolph-Perkins Co., engineers, has been nominated (equivalent to election) vice-president in charge of industrial development and public improvements of the Chicago Association of Commerce. Major Randolph has served on ten committees since 1915.

WILLIAM J. GRAY, who for the past ten years has been civil engineer in the U. S. Engineers office at Wilmington, Del., has resigned to become superintendent of the water-works at Springfield, Mo., for George West & Son of Portland, Maine.

FRANK E. SHEPARD, who was president of the Denver Engineering Works until it consolidated with Stearns

Roger Manufacturing Co., and a consulting engineer since that time, has been appointed superintendent of the Denver Mint. Mr. Shepard graduated from the Massachusetts Institute of Technology in 1887 as a mechanical engineer.

ALEXANDER POLLOCK has been appointed field engineer by the zoning commission of Denver, Colo. He will check up the various types of buildings and work in conjunction with the commission toward the perfecting of a new zoning ordinance.

DWIGHT P. ROBINSON & Co., INC., of New York, has opened an office in Atlanta, Ga., in the Healey Bldg., with W. RAWSON COLLIER in charge. Mr. Collier for many years was with the Georgia Ry. & Power Co. and more recently with the Poughkeepsie Gas & Electric Co. He is a graduate of Massachusetts Institute of Technology.

WILLIAM OEHRLI, formerly with the George A. Fuller Co. and recent manager of George A. Fuller Co. of the Orient, Ltd., announces the opening of an office at 342 Madison Ave., New York City, where he will transact his business of building construction.

Obituary

COL. ARCHIBALD O. POWELL, of the firm of Powell and Jacobs, consulting engineers, Seattle, Wash., died suddenly at his home in that city, Nov. 18. Col. Powell was born in Milwaukee, Wis., and graduated from the University of Wisconsin in 1880. He was for many years attached to the U. S. Engineers office with headquarters in St. Paul. In 1906 he moved to Seattle to take charge of the original Lake Washington Canal Project and upon completion of that engagement entered private practice as a consulting engineer, specializing in river and harbor work. He is a past-president of the Pacific Northwest Society of Engineers and of the Seattle Section, American Society of Civil Engineers. He served as a captain of engineers in the Spanish-American War and as a Lieutenant-Colonel of Engineers in the World War.

THOMAS J. WYCHE, San Francisco, Calif., consulting engineer for the Western Pacific Ry., died recently, at the age of 64 years. He was a native of Mississippi and a graduate of the University of the South. Mr. Wyche built many large water systems for the Union Pacific R.R., and tunnels for the Western Pacific at Sherman and Aspen, Colo.

WILLARD A. SMITH, publisher of the *Railway Review*, who died at Evanston, Ill., Nov. 29, was known specially for his work as chief of transportation exhibits at the Columbian Exhibition, Chicago, 1893; Louisiana Purchase Exhibition, St. Louis, 1904, and Paris Exhibition of 1900. Mr. Smith was born at Kenosha, Wis., in 1849. He was an affiliate of the American Society of Civil Engineers and a member of the Western Society of Engineers. He was prominent in the work of the Railway Master Mechanics and Master Car Builders Association before they were absorbed as the mechanical section of the American Railway Association.

On Making Concrete Road Finishers and Subgraders Do Their Best Work

Lion Gardiner, Vice-President
Lakewood Engineering Co.,
Tells How Sales Are Followed
Up by Field Inspection and
Constructive Suggestions on
Operating Methods.

APERUSAL of the various state highway specifications for concrete roads issued during the past five or six years indicates clearly the increased attention which is being given to preparing the subgrade, setting the forms and finishing the concrete. The development of machinery and equipment for doing this work has made possible reduced operating costs for the contractor and at the same time has given the

same sense that metal or wood forms on monolithic concrete construction produce a column, lintel or arch. Strength and accuracy of this mold or form, both from the standpoint of the highway department and the contractor, are essential.

"A manufacturer of equipment used in forming this mold," said Mr. Gardiner, "has a two-fold responsibility: First, to produce a machine which operates to give the results desired; and, second, to teach its use and function so that the contractor may produce in the finished work and in an economical manner the qualities of road surface and slab required by the specifications. The service on the operation of Lakewood equipment begins with the sale. Our salesmen must know not only the advantages of the finishing machine, subgrader or road forms, but must also be thoroughly acquainted with the limitations in operation of any unit. The sale

FINISHING MACHINES CAPITALIZE ADVANTAGES OF DRY CONCRETE WITHOUT MATERIALLY INCREASING LABOR COSTS OF SPREADING AND TAMING

highway departments and the public longer-lived roads. In this movement the Lakewood Engineering Co., of Cleveland, has been active, not only in designing equipment for building better roads, but also in helping contractors operate their plant so as to realize from it the maximum in quality and quantity of work. The result has been the development, by the Lakewood organization, of a definite policy of field service. From Lion Gardiner, vice-president of the company, *Engineering News-Record* has obtained the following notes on how this service functions:

SUBGRADE A VITAL PROBLEM

A completed subgrade upon which the side forms are set is in effect a mold or form to contain the concrete and produce an accurate concrete slab in

of a machine for a job necessarily imposes a responsibility for satisfactory operation."

For instance, the sale of a road-finishing machine necessitates making sure that the road forms which will carry the machine are substantial and that the soil upon which they will be set has the proper bearing power to hold them in alignment under the action of the finisher or subgrader. Further, such a sale, as interpreted by Mr. Gardiner, means that if there are any local conditions on the job which would work against the satisfactory operation of the finisher in any way they should be pointed out to the contractor by the manufacturer's representative so that, if necessary, correction can be made.

The responsibility of furnishing road

building equipment which fails to perform satisfactorily at a critical time, thereby holding up the job and allowing the contractor's overhead expense to pile up at a tremendous rate, is a large one. This responsibility is further increased by the fact that the construction season in most localities is short—scarcely more than 100 working days a year—and time lost due to faulty operation of equipment cannot be regained.

Furthermore, it is the Lakewood company's experience that the servicing of road-building equipment is complicated because the contractor's organization is often not a stable one. Since the construction season lasts only part of a year the organization has to be broken up at the close of the season and the operators of the various machines are frequently changed as a result.

CHECKING UP ON OPERATION

"The continued and increased sale of our equipment," Mr. Gardiner continued, "depends upon its satisfactory performance, and to insure such satisfactory performance under the conditions outlined we keep on the road during the active construction season field men whose duty it is to check up the operation of our units. This inspection is rendered not only at the request of an individual contractor, but is systematically made so that we have a fairly accurate record of the performance of all of our equipment in any territory.

"These inspectors visit the work and advise the operator and the contractor concerning the use of the machine, its adjustment, or repair. Besides having contact with the contractor and his men in charge of the equipment, our inspectors are also in touch with the engineers of the highway department and its inspectors. Thus we are assured that the requirements of the contractors and the State are being met.

"When such an inspection has been completed our man obtains the signature of the superintendent or the contractor himself, if possible, to an inspection report showing satisfactory operation of our equipment, and setting forth any suggestions which our man may have made for better operation. One copy of this form goes to the contractor's home office and another is sent to the state engineer in whose district the work is located as an indication to both that our interest in the equipment has not ceased with its sale.

"Aside from this provision of field service, every effort is made, whenever there is opportunity for mechanical improvement of the machines, to make the new parts interchangeable with the old, so that early model machine owners may benefit with new users."

The functions of the three units—finisher, subgrader and forms—are so closely related that service problems overlap. Nevertheless, in the following notes, an attempt is made to segregate and discuss the more important problems of each of these units:

THE FINISHING MACHINE

In so many states do the specifications require the finishing machine, because of the added strength and density of the concrete, that the Lakewood organization regards its responsibility as a double one, to the highway department and to the contractor. A con-

centrated and specific service, therefore, is insisted upon.

Mechanical finishing machines have made possible the use of drier concrete, with its attendant advantages of greater strength and density without increasing materially the labor cost of spreading, tamping, and finishing. Mechanical finishing machines, however, cannot produce a road surface more accurate than the side forms upon which they run. Specifications for road construction lay emphasis upon the smoothness of the surface, and require it be tested with a straight edge to detect any appreciable variation. High or low spots may be the cause of the rejection of part

MACHINE-MADE SUBGRADE FORMS ACCURATE MOLD FOR CONCRETE

of the work, or may make it necessary for the contractor to spend additional time in correcting them. It is essential, therefore, that the side forms be properly set, and particular emphasis is placed upon this point, not only by the manufacturer's field service men but also by his salesmen.

When a finishing machine is shipped to a contractor there is included with it a printed instruction book based upon the company's five years' field experience with this unit. This book contains information as to the assembly of the machine and its operation, and in addition tells about troubles which may be caused by lack of adjustment, the remedy and the lubrication of the machine. It gives pointers on the care and storage of the equipment during the winter months. Photographs and drawings are used to illustrate instructions, and bring out the points to be emphasized. It is realized that the operators of these machines will not have the time nor the inclination to study from a printed page the necessary steps in assembly, operation or adjustment. Therefore, the printed matter is kept to a minimum and consecutive steps are shown by pictures.

In addition to sending such an instruction book to the job with the machine, another copy is sent at the time of shipment to the home office of the contractor, so that the information will reach the contractor himself as well as his operator. The points in this instruction book are reiterated by both the Lakewood company's field-service men and its salesmen, who also make it a

point to visit the job in operation after the equipment is sold. Some of these important points are:

1. Set your forms well, and see that there is a good foundation for them.

2. Some hand spreading must be done ahead of the strike-off of the machine, as it is not possible for the finisher to spread a bank of 6 in. or more of concrete ahead of it without causing unevenness in the road.

3. Control the water supply on the mixer so that batches are maintained at a uniform consistency.

4. When placing concrete on grades uniformity of mix is of even more importance than on level work, because upon it depends the smooth-riding surface that must be obtained.

5. Clean the concrete off the machine at night. Do not allow 200 or 300 lb. of concrete to collect on the strike-off and tamping members.

6. Lubricate thoroughly.

7. A set of important spares is sent with the machine, and when one is used see that it is replaced immediately to avoid any possibility of a delay in your work.

8. Keep the float belt clean and flexible.

9. Check the finished work frequently to see that the desired results are being obtained. With some consistencies of concrete it is necessary to set the strike-off blades higher or lower than for others.

In addition to the foregoing points attention is directed to the use of the machine on pavements built under modified or changed specifications. For instance, the practice of building roads in half-widths brought about a specific problem to be met with the finisher. This was done by providing a special set of wheels to be used when finishing the second half of the road. The first slab is finished as any standard pavement. For the second slab the outside wheels of the finisher run on the road form, and are doubleflanged. The inside wheels run on the first slab and are flat tread. The working out of this method for best results means that the manufacturer's service men must be thoroughly posted upon its application and any special problems to be encountered.

THE SUBGRADER

The function of the mechanical subgrader is to plane or trim the subgrade to the final cross-section required, and upon its proper functioning depends the accuracy with which the road slab conforms to the specifications. The subgrader travels on the side forms, and the same necessity of seeing that they are well set obtains as for the finisher. The variety of soils upon which the subgrader is used requires that field men know how such different soils should be handled. With some it may be necessary to sprinkle the subgrade before the final cut is made. With others such sprinkling might be a detriment rather than a help. Speaking of practical points in subgrader operation Mr. Gardiner said:

"The subgrader is intended primarily for the final fine grading, but often the

men on the job, seeing how ruggedly the machine is built, attempt to take cuts which are entirely too deep. Considering an 18-ft. road a cut $\frac{1}{2}$ or $\frac{3}{4}$ in. deep for its full width produces considerable material to be removed or drifted to the low spots. Very often it is found that the contractor is not obtaining full advantage of his subgrader because he is attempting to take his first cut too deep. The subgrader serves as a marking templet to indicate high and low spots, and makes for efficiency in moving earth from the high to the low spots if the first cut is not too deep.

EQUALIZING CUTS AND FILLS

The operation of the subgrader for the first time so that the blades will cut the top of the high spots will indicate immediately where fills must be made. If the cut is too deep this advantage is lost. Further, moving the material which is cut from the high spots to the low spots on the subgrade makes it unnecessary to bring in material from outside the forms. With the low spots filled and rolled the function of the subgrader is to plane the subgrade $\frac{1}{4}$ in. at a time, if necessary, until it conforms to the required depth at all points. To get full advantage from the subgrader it is also necessary that forms be set well ahead of where concreting is in progress, so that a sufficient amount of subgrade can be completed at one operation."

Some instances are found by Lakewood service men where contractors owning subgraders are not using them because they do not appreciate the fact that this tool can be used in conjunction with motor-truck haul of materials without stopping operations. "Very often," Mr. Gardiner continued, "it is possible to use a subgrader in the morning, at noon and in the evening, when hauling is not in progress, so that sufficient subgrade can be completed for the entire day's run. Then there are some instances where instructions are given about moving the subgrader to one side of the road, after it has completed its operation, so as to clear the right-of-way for the trucks. Even the method of handling such a simple operation may mean a saving to the contractor. Our men are very often able to demonstrate on a job the advantage of carrying two short timbers upon the subgrader upon which it is lowered and moved to one side of the road when it is desired out of the way.

"The length of hitch used has considerable influence upon the results obtained. Too short or too long a hitch will cause difficulty in side play, with resulting damage to forms. We, therefore, furnish with the machine the proper length cable to be used and our service men keep the contractor posted on this point."

ROAD FORMS

The advent of mechanical finishing of the subgrade and the mechanical finishing of the surface of the concrete slab, has increased the importance of proper setting of the forms. They have become not only the mold for the side of the slab, but a templet from which the subgrader shaves the subgrade to the proper depth and the finisher strikes off, tamps and belt-floats the concrete to the proper height. Accordingly, a firm foundation for road forms is infinitely more important than before, as

To Manufacturers of Machinery and Materials

You received from "Engineering News-Record" last week a letter requesting a brief statement covering the outstanding improvements made in your products during 1923.

This information is desired for the

Annual Review of Machinery and Materials

to appear in the first issue of the New Year, Jan. 3, 1924.

It is important, if the developments in your machines or materials are to receive adequate editorial treatment, that you send us the information desired as soon as possible—in any event not later than Dec. 17.

Paving Brick Shipments Continue Heavy

That the paving season because of a wet spring generally and a late start, is running later in the fall this year than is customary is indicated by the continued heavy shipments of vitrified paving brick reported by the National Paving Brick Manufacturers Association. Shipments for the month of October were 34,287,000 brick as against 34,761,000 for September. The total number of brick manufactured was 34,317,000 for October and 34,457,000 for September.

low spots at the joints or in the forms, will immediately reflect irregularities in the subgrade and the surface of the road. Service on road forms has to do primarily with seeing that they are properly staked and properly aligned.

Manufacturers during the past year have doubled not only the thickness of road forms to get strength, but also have increased the width of the form base to give added bearing surface. It devolves upon the contractor, Mr. Gardiner believes, to prepare the grade to receive these forms so that the required accuracy is maintained and a good support given to bear the weight of the subgrader and finishing machine.

Not only has Lakewood's field service had to do with the proper setting of forms, but the company's engineering department has spent considerable time in the development of its own form and the study of the service which it must meet. In an effort to insure the rigidity of the forms the company has manufactured sections 12-ft. in length against those of 10-ft. ordinarily sold, thereby reducing the number of joints required. Experience has further developed a round-top or line-point surface form upon which the concrete cannot lodge to cause irregularities in the surface of the road as the finishing machine goes over them.

"To sum up," Mr. Gardiner concluded, "it is the policy of our company to see to it that equipment is sold only with the proper understanding on the part of the contractor as to its performance, and that after the sale is completed full and sufficient instructions are given either by printed books, correspondence or personal visits to the end that the units function to the entire satisfaction of all concerned."

Sanction Sought for Joint Sales Organizations

Movement on Foot to Amend Webb Act—Initial Action on Construction Materials Probable

Washington Correspondence

WHILE it is too early to predict what concrete action will be taken by industry following the discussion at the Department of Commerce of selling combinations, it is known that much interest is being manifested in the general question. Definite steps are expected shortly because of the need for prompt action if economies are to be effected in handling reconstruction sales in Japan. The time also is opportune to secure an amendment to the Webb-Pomerene act, if it should be found desirable to organize under that statute.

The agitation at this time for joint sales organizations or selling corporations comprised of non-competing units is more than an effort to handle Japanese business in the most efficient way. It is being considered in connection with the movement to expand all of our export activities. It is recognized that all possible economies must be secured if we are to compete in the world markets.

MAY AMEND WEBB ACT

Joint sales organizations can be established abroad by non-competing industries without legislation. There are some who believe, however, that advantages would accrue were it possible to organize non-competing activities into Webb law corporations. It is known that the Webb act is to be taken up for amendment at this session of Congress. The principal amendment which will be proposed is to permit of combinations for import purposes. These combinations doubtless will be limited to commodities produced entirely or in great part abroad, in the handling of which artificial price levels are maintained.

While many industries are interested in these proposals, the first definite step is likely to be taken by the manufacturers of construction materials. It is evident that important economies could be effected were sales of lumber, steel, sash, doors, plumbing, glass, paint and other building materials handled through the same agency. If organization along those lines expedites and makes more efficient the handling of the Japanese orders at this time, it is argued that it should be equally useful in handling other export business.

In the export trade American manufacturers are having to meet competition from countries where it is entirely legal to combine. The depression in Great Britain is forcing large-scale combinations, which mean reduced overhead charges and the elimination of the less efficient production units. One of the principal savings is in selling costs. Knowledge and experience in manufacture can be pooled. Research can be undertaken on a more ambitious scale.

While American manufacturers may not take advantage generally of many of these economies by reason of our anti-trust statutes some of them can be secured in the handling of exports. It is believed that Congress is disposed to consider sympathetically various amendments to the Webb-Pomerene Act.

"Commerce Yearbook" Presents Survey of American Industry

A new government service to business has just been made available in the form of the "Commerce Yearbook," prepared by the Department of Commerce to meet demands of American business men, bankers, economists and trade association executives for an authoritative review of the economic year throughout the world from the point of view of American industry. The first issue covers the year 1922 and the early part of 1923. It comprises 692 pages, containing, in addition to the text, many charts, maps and tables of statistics.

The book is intended not merely as a reference source but to be read for general commercial information on such outstanding facts of trade as production, price changes and market conditions. Among the chapters dealing with the nation's important industries is one on the "Construction Industry."

Business Notes

LAKEWOOD ENGINEERING Co., Cleveland, manufacturer of concrete chuting equipment, steel road forms, subgraders and finishing machines, announces that the sale of its equipment has been placed in the hands of **Brown & Sites, 30 Church St., New York, N. Y.** From 1912 to 1918 this company handled the Lakewood line of construction and paving equipment in the New York territory, so that, in resuming this representation, the **Brown & Sites Co.** has full knowledge of Lakewood products and policies. Special attention will be devoted to giving service to contractors who purchase this equipment.

Equipment and Materials

Imported Trass Available in U. S.

Recent importations from Germany now make available for the first time on a commercial scale in the United States supplies of trass, a mineral product of volcanic origin which, when mixed with portland cement, is claimed to produce concrete exceptionally hard, watertight and resistant to acid and sea-water. The material has been extensively used for years past in European practice for concrete dams, pipe and structures in sea water. The distribution of trass in the United States is being handled by **Emil Stahl, 531 Palisade Ave., Jersey City, N. J.**

Publications from the Construction Industry

Snow Plows—**GOOD ROADS MACHINERY Co., Inc.,** Kennett Square, Pa., has issued an illustrated 7-p. bulletin on its Champion snow-plows for attachment to the front ends of heavy tractors. The plow consists of an inclined platform carried on rollers and sleds with a V-type moldboard mounted on it on a push frame arranged for attaching to the tractor.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 305 to 320, are the following:

School, New York, N. Y., to **G. Colon & Co., \$1,089,000.**

Apartment Hotel, St. Louis, Mo., to **P. J. Bradshaw, \$1,500,000.**

Factory, Rocky Hill, Conn., to **Dennis O'Brien & Sons Co., \$1,000,000.**

Apartment, New York, N. Y., **A. D'Antona** by day labor, **\$1,000,000.**

Apartment, New York, N. Y., to **Turner Constr. Co., \$1,000,000.**

Winter Building Advocated

That the usual summer shortage of skilled building trades mechanics is becoming more pronounced each year, is the opinion of **Monks and Johnson, architects and engineers, of New York and Boston.**

"Each spring and summer," they point out, "see contractors offering inducements in the form either of premium wages or assurance of overtime at the regulation rate in order to secure workmen. There is little or no opportunity to select artisans for the quality of their workmanship. All are employed and all are eagerly sought by employers. Inefficiency abounds and costs mount high.

"In the winter, however, there is unemployment. A chart recently published by the Boston Building Congress gives the percentage of employment during the months of December, January and February as follows:

Trade	Per Cent
Common labor	40
Carpenters	50
Masons	25
Lathers	40
Plasterers	50
Painters	25

"Experience has shown that winter building is possible, and in most kinds of construction without sacrifice of quality. There remain therefore only considerations of economy. It would cost more to build in winter, were other factors the same, than in the warmer months. Materials must be heated and protection provided to prevent fresh concrete and mortar from freezing. Numbed fingers are not nimble. Snow must be removed. There is a well recognized additional expense involved in these factors. But there are factors on the other side.

AMPLE SUPPLY OF LABOR IN WINTER

"In the winter there is ample supply of labor. Wage premiums and overtime assurances are unnecessary. Selection of artisans is possible and competition spurs them to greater efforts. The market for building materials almost invariably eases up in the late fall and winter. Shrewd purchasers can buy for midwinter delivery substantially below spring and summer prices. Contractors anxious to keep their organizations functioning and thus meet the cost of that burlesque of business executives, overhead, are often glad to forego in the winter months further profit. These factors all favor winter building and may balance or outweigh the cost of heating and protection."

Next week—Production and stocks of basic building materials in several important centers.

Business Briefs

Call money easier at 5@4½ per cent. Time money quiet and unchanged at 5@5½ per cent.

Commercial paper unchanged at 5@5½ per cent.

Foreign exchange advances and then declines. Sterling, \$4.34½; last week, \$4.383; year ago, \$4.531. Franc, \$0.05404; last week, \$0.05453; year ago, \$0.07021. Lire, \$0.0434; last week, \$0.0435; year ago, \$0.05012.

Common Brick Imports Increase

A total of 18,365,000 common brick was imported into this country, through the Port of New York, during the third quarter of the current year, as against 10,379,000 for the preceding quarter.

In *Engineering News-Record*, issue of Nov. 29, p. 911, the import total for the first quarter was incorrectly stated at 10,379.

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for, in Construction News, pp. 305 to 320, are the following:

Bank and Office, Dallas, Tex., Republic Nat'l Bank, \$1,500,000.

Apartment, Chicago, Ill., **R. W. Matteson, \$1,000,000.**

Ties, Montreal, Que., Canadian Pacific Ry., 6,000,000 ties \$4,000,000.

Mill, Temiskaming, Que., **L. N. Huard, \$1,000,000.**

Hotel, Memphis, Tenn., Southern Hotel Co., \$3,000,000.

Bank and Office, Buffalo, N. Y., Liberty Bank, \$2,000,000.

Hotel and Office, Philadelphia, Pa., Middle City Realty Corp., \$10,000,000.

Foreign Projects of Interest to Americans

A number of foreign construction projects which should be of interest to American engineers, contractors and manufacturers has been reported by the United States Department of Commerce. They are noted here, further information being available at the Bureau of Foreign and Domestic Commerce or its district co-operative offices, when a reference number is given.

Water for two Greek cities from artificial lake. Specifications are now available for examination by interested American firms. Reference No. 12,599.

Modern hotel for Czechoslovakia. Hotel along American lines to be erected in Prague. Estimated cost, \$2,500,000. Reference No. 12,558.

Subway to be built in Argentine city. A street car company plans to build a subway to take care of heavy business traffic. Reference No. 35X-A.

Power station to be built at Guadeloupe. Plant to furnish power for chocolate factory and light for two neighboring sections. Reference No. 111,348.

Value of November Contracts 16 Per Cent Heavier Than for Same Month Last Year

Total of 795 Awards During November. Average Value \$196,402, Compared With 699 in October, Averaging \$230,724

The total value of contracts awarded on large engineering construction projects, in the five November issues of *Engineering News-Record*, reached \$156,140,000 as compared with \$161,276,000 in the four issues of October. This represents an average weekly value of \$31,228,000 for November, against \$40,319,000 during the preceding month.

The weekly average of \$31,228,000 for the month of November represents

an increase in money value of nearly 16 per cent above the weekly average for the corresponding period in 1922.

Minimum costs observed in Construction News on each class of construction are as follows: Waterworks, \$15,000; other public works, \$25,000; industrial construction, \$40,000; and commercial buildings, \$150,000.

All classes of construction fell off during November with the exception of water-works, bridges, excavations, com-

mercial buildings and certain unclassified jobs. Water-works awards gained 72 per cent in total money value during the month, while bridges increased 42 per cent and commercial buildings, 20 per cent. Contracts awarded for excavations, drainage and irrigation, totaling \$2,749,000, were over three times greater than those for the preceding month.

Among the large projects awarded during October were the following: A central station at Davenport, Ia., \$10,000,000; bank and office building, Cleveland O., \$5,000,000; 5,000 tons of steel for shipping terminal, Seattle, Wash., \$4,000,000; filtration plant, Cleveland, O., \$2,885,000; hotel, Louisville, Ky., \$2,300,000; and a high school, New York, N. Y., \$2,145,000.

Engineering News-Record Construction Cost Index Number

December, 1923	217.30
November, 1923	220.90
December, 1922	192.60
Peak, June, 1920	273.80
1913	100.00

Engineering News-Record's Construction Cost Index Number dropped 3.6 points since last month, owing to decline in prices of lumber and cement. Prices of other basic building materials remained unchanged during the month. The average rate for common labor is still 54c. Thus, general construction cost is 13 per cent higher than one year ago and 21 per cent under the peak; it is 117 per cent above the 1913 level.

Engineering News-Record Construction Volume Index Number

Monthly	
November, 1923 (5 issues of E. N.-R.)	125
October, 1923 (4 issues of E. N.-R.)	127
November, 1922 (5 issues of E. N.-R.)	122
1913	100
Yearly	
1922 (entire year)	130
1921 (entire year)	88
1920 (entire year)	91
1913	100

Engineering News-Record's Construction Volume Index Number is 125 for the month of November, and 130 for the whole of 1922, as against 100 for 1913. This means that the actual volume of construction in 1922 (not the mere money-value of the contracts let that year) is 30 per cent above the volume of construction for 1913. Our monthly volume number, 125 for November, 1923, is really the increment of construction, and indicates the rate at which contracts are being let as compared with 1913 awards.

VALUE OF CONTRACTS LET IN THE UNITED STATES AND CANADA DURING NOVEMBER, 1923

Labor Rates and Conditions Throughout the Country

Wage increases reported during November were far in excess of reductions despite the seasonal slowing down in construction, the marked curtailment in the cotton textile output and a decrease in bituminous coal production. The advances occurred principally among steam and electric railway employees and in the printing industry.

Increased wages and higher living costs, particularly in food, clothing and fuel, are contrasted with the perceptible slowing down in general industrial activity. Proposed legislative action affecting tax reduction; soldiers' bonus; child labor; railroad, agricultural and immigration problems, is one of the
